Number of Figures: 8

Section 1: Chamber Characterization

The outdoor experiments were conducted using the University of Florida Atmospheric Photochemical Outdoor Reactor (UF-APHOR) dual chambers located on the roof of Black Hall at University of Florida, Gainesville, Florida (latitude/longitude: 29.64185°/-82.347883°). The total volume for the two half-cylinder shaped chamber is 52 m³ each. The surface to volume ratio is 1.65 m² m⁻³ for each chamber. The chambers are built with 0.13 mm FEP Teflon film. The meteorological parameters (i.e., temperature, relative humidity, sunlight spectrum and sunlight intensity) are monitored simultaneously both inside and outside the chambers using a hygrometer (CR1000 Measurement and Control System, Campbell Scientific) (temperature and humidity), a fibro-optical portable spectrometer (EPP2000, Stellar Net Inc., USA) (sunlight spectrum) and an ultraviolet radiometer (TUVR, Eppley Laboratory Inc.) (sunlight intensity). In addition, the wall loss rate constants of ozone, SO₂, H₂O₂ and HONO were measured via separate experiments. The rate constant of particle loss to the chamber wall was also measured for Arizona Test Dust (ATD) particles as well as the ammonia sulfate inorganic seeded aerosol. The particle loss rate was calculated for every 3 minutes within each particle size bin and then integrated to calculate an average particle loss rate. The typical particle distribution of ATD particles is shown in the Fig. S1.

Indoor chamber experiment

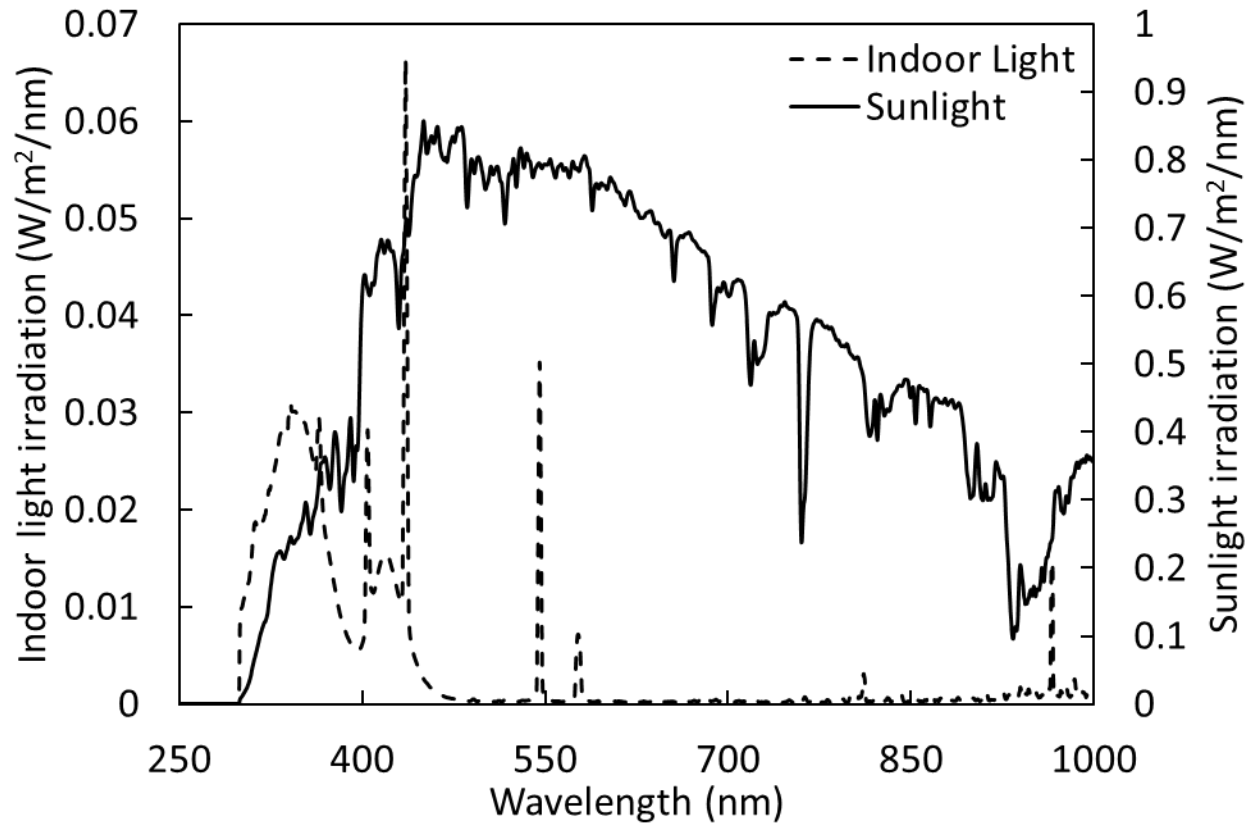

The indoor chamber experiments were performed in a 2 m³ Teflon indoor chamber equipped with UV lamps (Wavelength: 280nm – 900 nm) (Solarc Systems Inc., FS40T12/UVB). The RH and the concentration of trace gases and dust particles were controlled to variety specific experimental conditions. During the experiment, the gases were continuously measured directly from the indoor chamber using a gas chromatography-flam ionization detector (HP-5890 GC-FID), a fluorescence TRS analyzer (Teledyne Model 102E), and a chemiluminescence NO/NO_x analyzer (Teledyne Model T201). The suspend particles were continuously measured by a scanning mobility particle sizer (SMPS, TSI 3080, USA) and an Optical Particle Counter (OPC, TSI 3330, USA). The mass concentration of inorganic iron was measured using a Particle-Into-Liquid Sampler (Applikon, ADISO 2081) combined with Ion Chromatography (Metrohm, 761 Compact IC) (PILS-IC) for every 30 minutes.

Outdoor chamber experiment

The dual chambers were flushed and cleaned by the air purifier system (GC Series, IQ Air Inc.) for 2 days before each experiment. The background sulfate concentration was measured every time

before experiments. Non-reactive CCL_4 (400 ppb) was injected into the dual chamber to determine the chamber dilution factor. Due to the chamber dilution, ambient trace gases (i.e., CO , O_3 , CH_4 , HCHO and volatile organic compounds) outside the chamber are intruded into the chamber. The estimated concentration of background gases are 1.8 ppb CH_4 , 18 ppb HCHO , 6 ppb CH_3CHO , 0.1 ppb isoprene and 1 ppb HONO . The measurement procedures of gases and inorganic iron concentration were similar to that of indoor chamber experiments. The particle distribution was measured using the SMPS and the OPC. For measuring the total particle mass concentration, the suspended particles were collected on a 13mm diameter Teflon-coated glass fiber filter (Pall Life Science Pallflex, TX40HI20-WW) for 20 minutes. The filter mass difference was measured using a microbalance (MX5, Mettler Toledo, Columbus, OH). The temperature (T, K) and relative humidity (RH, %) in the dual chamber were monitored using a hygrometer (CR1000 Measurement and Control System, Campbell Scientific). For measuring the wavelength-dependent actinic flux, a fibro-optical portable spectrometer (EPP2000, Stellar Net Inc., USA) and an ultraviolet radiometer (TUVR, Eppley Laboratory Inc.) were used.

Figure S1

- 5 Figure S1. Light irradiation of the indoor–UV light and the sunlight measured with a fibro–optical portable spectrometer (EPP2000, Stellar Net Inc., USA). The sunlight irradiance was measured on April 20th, 2016 in University of Florida Atmospheric Photochemical Outdoor Reactor, Florida, USA (latitude/longitude: 29.64185°/-82.347883°).

Figure S2

Figure S2. Typical particle size distribution of Arizona Test Dust particles for dust concentration of $74 \mu\text{g m}^{-3}$ for the experiment on November 22, 2016. The particle number concentration was measured by combining a scanning mobility particle sizer (SMPS, TSI 3080, USA) and an Optical Particle Counter (OPC, TSI 3330, USA) using a Multi-instrument Manager (MIM2TM) Software provided by TSI.

Figure S3

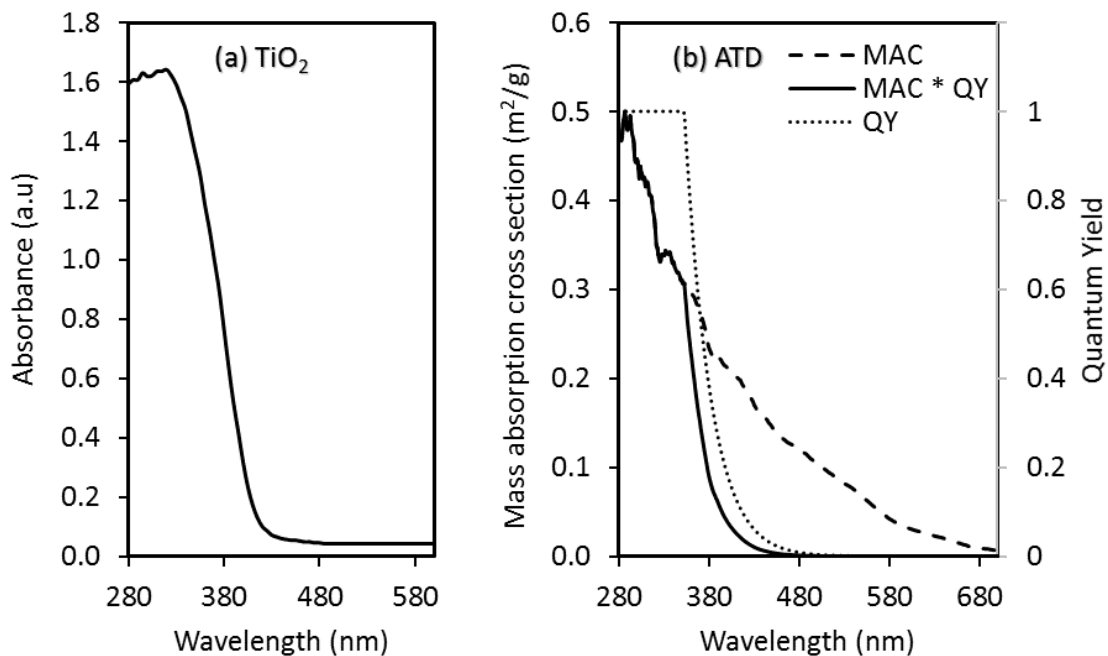

Figure S3. (a) Light absorption of TiO₂ (Reyes–Coronado et al., 2008) (b) The mass absorption cross section (MAC) and the quantum yield (QY) of Arizona Test Dust particles were multiplied to calculate the photocatalytic rate coefficient. The quantum yield of Arizona Test Dust particles was derived from the absorption spectrum of TiO₂.

Figure S4

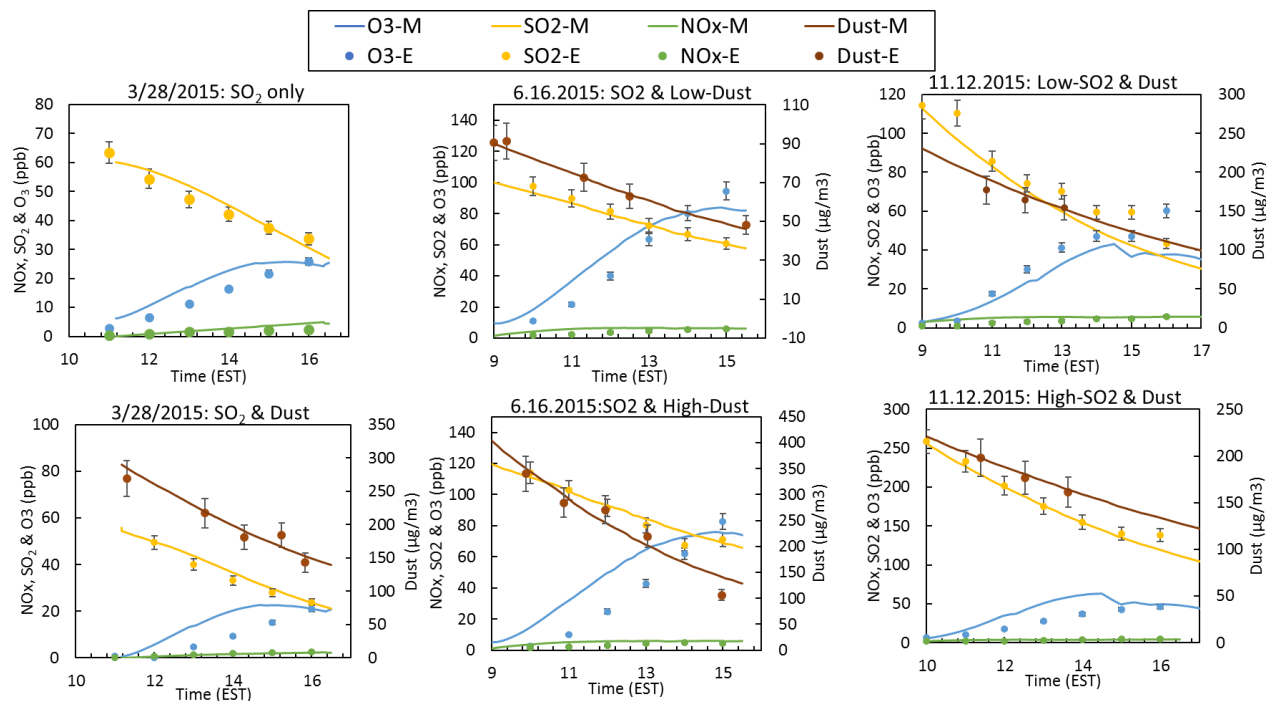

Figure S4. Simulated Ozone, NO_x, SO₂, and Dust concentration compare to outdoor experimental observation for Outdoor experiment (3/28/2015, 6/16/2015 and 11/12/2015). “E” denotes the experimentally observation and “M” denotes the model–predicted concentration of trace gases as well as ATD particles. All the simulations included the chamber dilution and the wall process of gaseous compounds and particles. The errors associated with the observation of SO₂, NO_x, O₃ and dust particle mass concentration were $\pm 0.9\%$, $\pm 12.5\%$, $\pm 0.2\%$ and $\pm 6\%$, respectively.

Figure S5

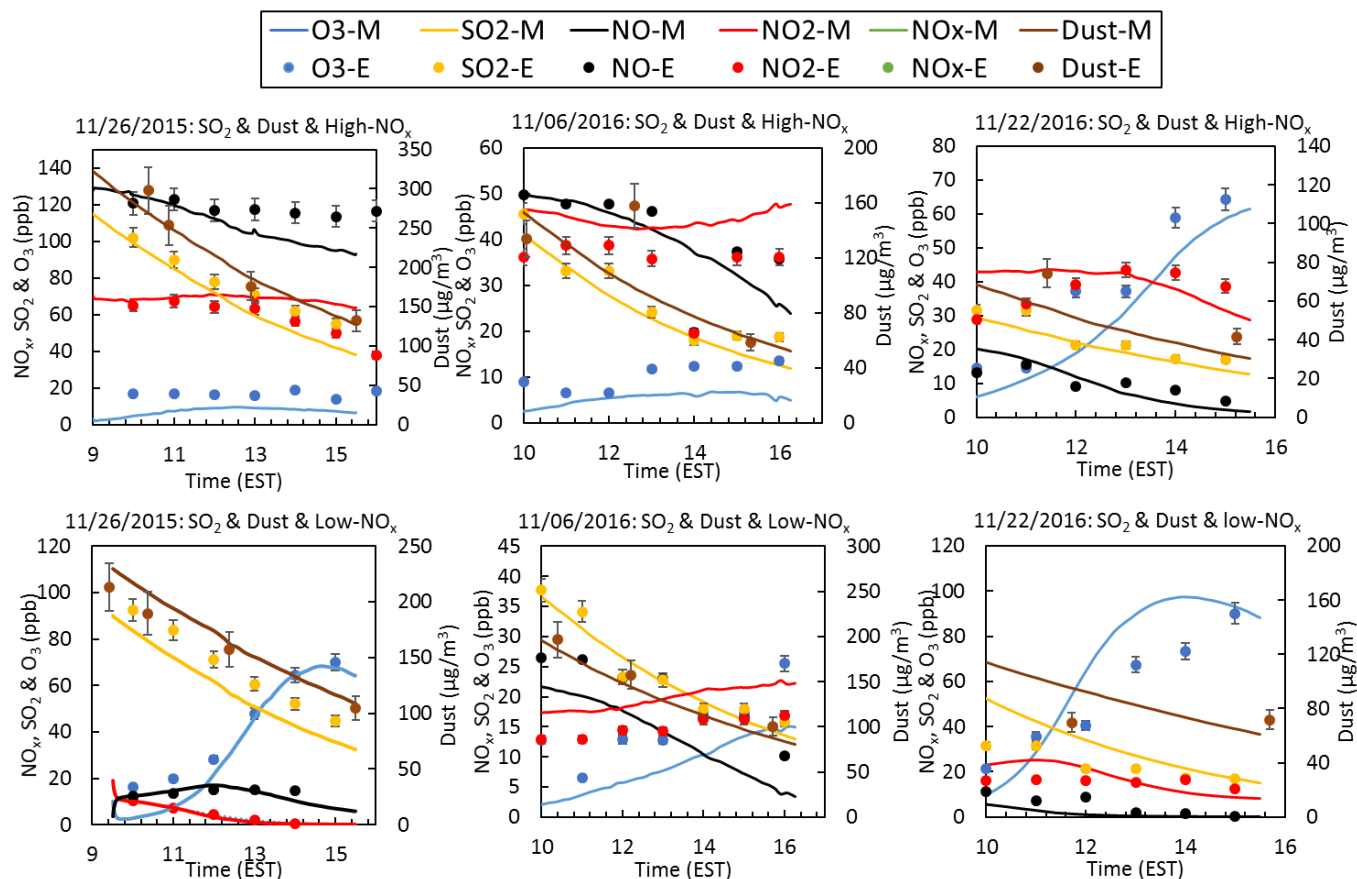

Figure S5. Simulated Ozone, NO_x, SO₂, and Dust concentration compare to outdoor experimental observation for Outdoor experiment (5/11/2015 and 11/26/2015). “E” denotes the experimentally observation and “M” denotes the model–predicted concentration of trace gases and ATD particles. All the simulations included the chamber dilution and the wall process of gaseous compounds and particles. The errors associated with the observation of SO₂, NO, NO₂, O₃ and dust particle mass concentration were ±0.9%, ±12.5%, ±6.9%, ±0.2% and ±6%, respectively.

Figure S6

(a) Total solar UV radiation

(b) Temperature and humidity

5

Figure S6. Time profile of (a) total solar UV irradiation and (b) temperature and humidity measured on November 22, 2016 at University of Florida Atmospheric Photochemical Outdoor Reactor, Florida, USA (latitude/longitude: 29.64185°/-82.347883°). The total solar short-wave radiation (0.295 to 0.385 μm) was measured using an ultraviolet radiometer (TUVR, Eppley Laboratory Inc.) inside the chamber. The temperature and humidity are continuously monitored inside the chamber using a hygrometer (CR1000 Measurement and Control System, Campbell Scientific)

Figure S7

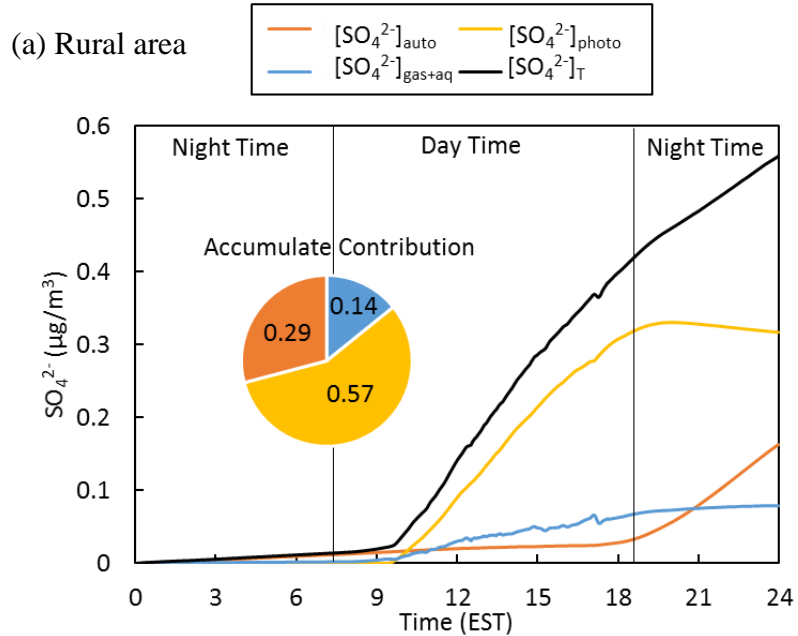

Figure S7. The uncertainty of simulated total sulfate to the variation of selected model parameters. The percent change of the total sulfate was simulated using AMAR model after each parameter was increased or decreased by a factor chosen from the error associated with the parameter. The chamber simulation is conducted with 100 ppb of initial SO_2 , 2 ppb of initial NO_2 , 2 ppb of initial O_3 and $200 \mu g m^{-3}$ of ATD particles at $T = 298K$ and $RH = 40\%$ under ambient sunlight on November 22, 2016. NO_x (rate of flux = $2.7 \times 10^6, s^{-1}$) and isoprene ($2.7 \times 10^6, s^{-1}$) were constantly added to chamber for the dilution effects. The simulation was performed without considering the particle loss to the chamber wall.

Figure S8

5 (b) Urban area

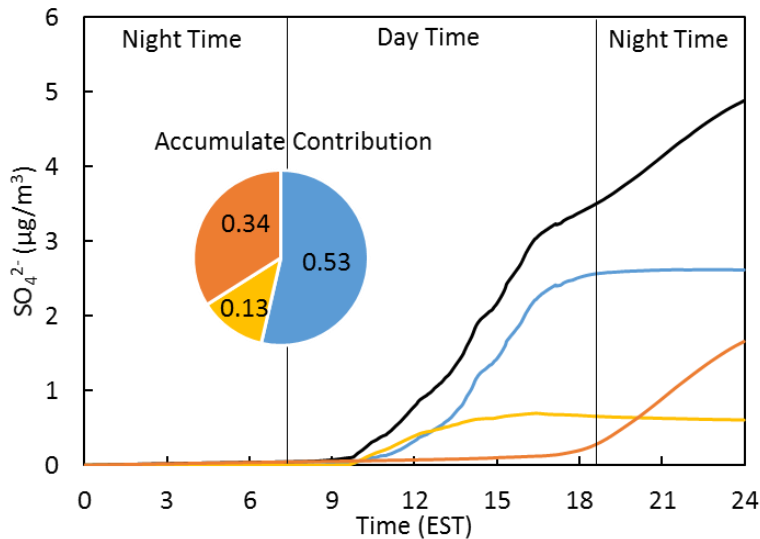

Figure S8. 24 hours simulation of attribution of sulfate formation under the rural (Fig. S8(a)) and polluted urban environment (Fig. S8(b)) using AMAR model. The total sulfate is simulated to show the composition including the sulfate formed from non-dust chemistry ($[\text{SO}_4^{2-}]_{\text{aq}} + [\text{SO}_4^{2-}]_{\text{gas}}$), from dust-phase autoxidation ($[\text{SO}_4^{2-}]_{\text{auto}}$), and from dust photochemistry ($[\text{SO}_4^{2-}]_{\text{photo}}$). The meteorological parameters (i.e., temperature and humidity) are obtained from outdoor chamber experiment (11.22.2016, Table 2). The particle loss to the chamber wall was not considered into the simulation while the dilution process was included.

10 In Fig. S8(a), $200 \mu\text{g m}^{-3}$ of ATD particles, 2 ppb of initial SO_2 , 5 ppb of NO_x and 20 ppb of isoprene were set for the simulation of rural condition.

15 In Fig. S8(b), $200 \mu\text{g m}^{-3}$ of ATD particles, 30 ppb of initial SO_2 , 40 ppb of NO_x and 30 ppb of isoprene were set for the simulation of polluted condition.

12	Dust + <i>hν</i> → Dust + e _h		j _[ATD]			estimated
13	e _h → energy	i	1×10 ⁻²			estimated
14	e _h + O ₂ → OH(d)	j	1×10 ⁻²²	2.3		estimated
15	SO ₂ (d) → SO ₄ ²⁻ (d)	i	5×10 ⁻⁶			estimated
16	SO ₂ (d) + OH(d) → SO ₄ ²⁻ (d)	i	1×10 ⁻¹²			estimated
17	SO ₂ (d) + O ₃ (d) → SO ₄ ²⁻ (d) + O ₂	i	2×10 ⁻¹¹			estimated
18	e _h + O ₃ (d) → OH(d) + O ₂	i	1×10 ⁻¹²			estimated
19	NO ₂ (d) → NO ₃ ⁻ (d)	i	6×10 ⁻⁵			estimated
20	e _h + NO ₂ (d) → HONO(d)	i	6×10 ⁻¹²			estimated
21	HONO(d) + <i>hν</i> → OH(d) + NO		j _[HONO]			Stockwell and Calvert, 1978; Atkinson et al., 1997
22	NO ₂ (d) + OH(d) → NO ₃ ⁻ (d)	i	1×10 ⁻¹⁰			estimated

Table S1. (continued)

Reaction	Rate constant ^a	k ₁	k ₂	k ₃	Note
23	$\text{NO}_3^-(\text{d}) + \text{Salt}(\text{d}) \rightarrow \text{NO}_3^-(\text{d_salt})$	i	1×10^{-8}		estimated
24	$\text{SO}_4^{2-}(\text{d}) + \text{Salt}(\text{d}) \rightarrow \text{SO}_4^{2-}(\text{d_salt})$	i	1×10^{-8}		estimated
25	$\text{NO}_3^-(\text{d_salt}) + \text{SO}_4^{2-}(\text{d}) \rightarrow \text{SO}_4^{2-}(\text{d_salt})$	i	4×10^{-13}		estimated

Reaction	Rate constant ^a	Note	
	Wall loss ^k		
1	$\text{SO}_2 \rightarrow$	(1.3RH + 3.3) × 10 ⁻⁶	For indoor chamber simulation; measured
2	$\text{O}_3 \rightarrow$	7 × 10 ⁻⁵	For indoor chamber simulation; Chen and Jang, 2012
3	$\text{SO}_2 \rightarrow$	(0.7RH + 1.7) × 10 ⁻⁶	For outdoor chamber simulation; estimated
4	$\text{O}_3 \rightarrow$	3.5 × 10 ⁻⁵	For outdoor chamber simulation; estimated
5	<i>Dust</i> →	1 × 10 ⁻⁵	Measured
6	$\text{SO}_4^{2-}(\text{aq}) \rightarrow$	5 × 10 ⁻⁶	Measured

^a The unit of reaction rate constants is s⁻¹ for first-order reactions, cm³ molecule⁻¹ s⁻¹ for second-order reactions and cm⁶ molecule⁻² s⁻¹ for third order reactions. The unit of the rate constants for the dust sorption reactions is m³ m⁻² s⁻¹.

^b The rate constant parameters of SO₂ oxidation in gas phase are taken from previous studies as shown in note of each reactions and can be also found in Chen and Jang (2012). T (K) is the temperature.

5 ^c $V = N_A \times V(\text{aq})$, where N_A (6.022 × 10²³ molecule mol⁻¹) is the Avogadro constant and $V(\text{aq})$ (L cm⁻³) is the volume concentration of inorganic salt seeded aqueous phase in the air. The unit of the chemical species in the aqueous phase is mole per cm³ of air for the model simulation. The rate constant parameters of reactions in aqueous phases are updated from previous studies (Liang et al., 1999). The detailed citation of each reactions was shown in the notes. The concentration of $V(\text{aq})$, H₂O(aq), H⁺ and OH⁻ are calculated using E-AIM II (Clegg et al., 1998; Wexler and Clegg, 2002; Clegg and Wexler, 2011).

10 ^d The partitioning rate constant of gas to the aqueous phase is derived from Henry constant (mol atm⁻¹). ρ_{in} is the density of the inorganic salt seeded aerosol and is calculated using E-AIM II (Clegg et al., 1998; Wexler and Clegg, 2002; Clegg and Wexler, 2011).

^e The unit of dust for the model is mass concentration (μg m⁻³). During simulation, the concentration of dust is multiplied by a factor of 2.45 × 10¹⁰ to have same magnitude with other gaseous species.

^f Rate constant $k = k_1 \sqrt{8RT/(\pi MW)} f_{dust,M2S} / 4$, where $f_{dust,M2S} = 3.066 \times 10^{-6} (m^2 \mu g)$, $R = 8.314$ is the ideal gas constant and MW is the molecule weight of chemical species.

^g Rate constant $k = k_1 \exp\left(-\frac{k_2}{T}\right) / (F_{water}(1 + k_3/[H^+]))$, where $F_{water} = \exp(4.4RH) + 3.7\exp(4.4RH) \frac{[NO_3^-]}{[Dust]} + \frac{M_{in,water}}{[Dust]}$. $[H^+]$ and $M_{in,water}$ are the concentration of proton and water in dust phase, respectively, and are dynamically calculated using E-AIM II.

5 (Clegg et al., 1998;Wexler and Clegg, 2002;Clegg and Wexler, 2011).

^h Rate constant $k = k_1 \exp(-k_2/T)$.

ⁱ Rate constant $k = k_1$.

^j Rate constant $k = k_1 \exp(k_2)$.

^k The wall loss factors for the model simulation are only valid for the indoor and outdoor chambers used this study. The loss factors of
10 gases and particles may be varied for different chamber systems.
