37 1 Calibration and Operation of the CCN counter

38 The system used to measure size-resolved CCN spectra during GoAmazon 2014/5 is shown
39 in Fig. S1, and the operation sequences of DMA classified particle diameter, Q_{CCN} and ΔT are
40 present in Fig. S2. The CCN counter was calibrated at each flow and temperature setting using
41 ammonium sulfate as an inorganic aerosol standard (Lance et al., 2006; Mei et al., 2013; Roberts
42 and Nenes, 2005; Shilling et al., 2007). As the temperatures at the top of the CCN counter
43 column (T_1) varies with room temperature, the calibration was repeated for each pair of Q_{CCN} and
44 ΔT over a range of T_1 typically encountered during GoAmazon 2014/5. The calibration results
45 are shown as a function of Q_{CCN} and ΔT conditions at $T_1 = 25^\circ\text{C}$ in Fig. S3, and the variation of
46 instrument supersaturation (SS) with respect to T_1 is present in Fig. S4. Instrument
47 supersaturation during the measurements was calculated using the Q_{CCN} , ΔT , and T_1 based on the
48 calibrations.

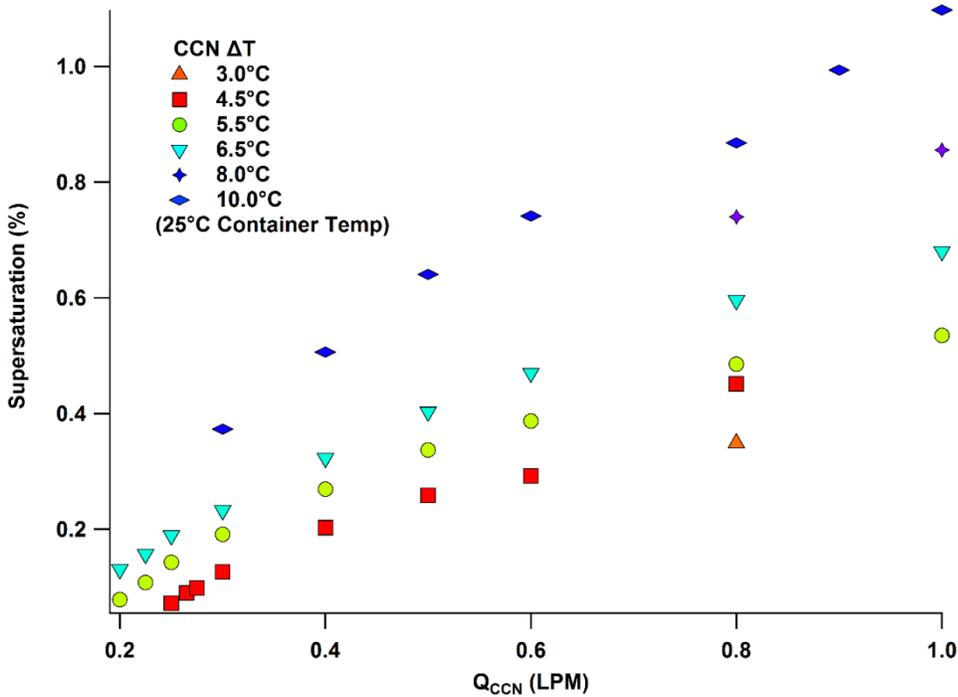

49

51 2014/5.

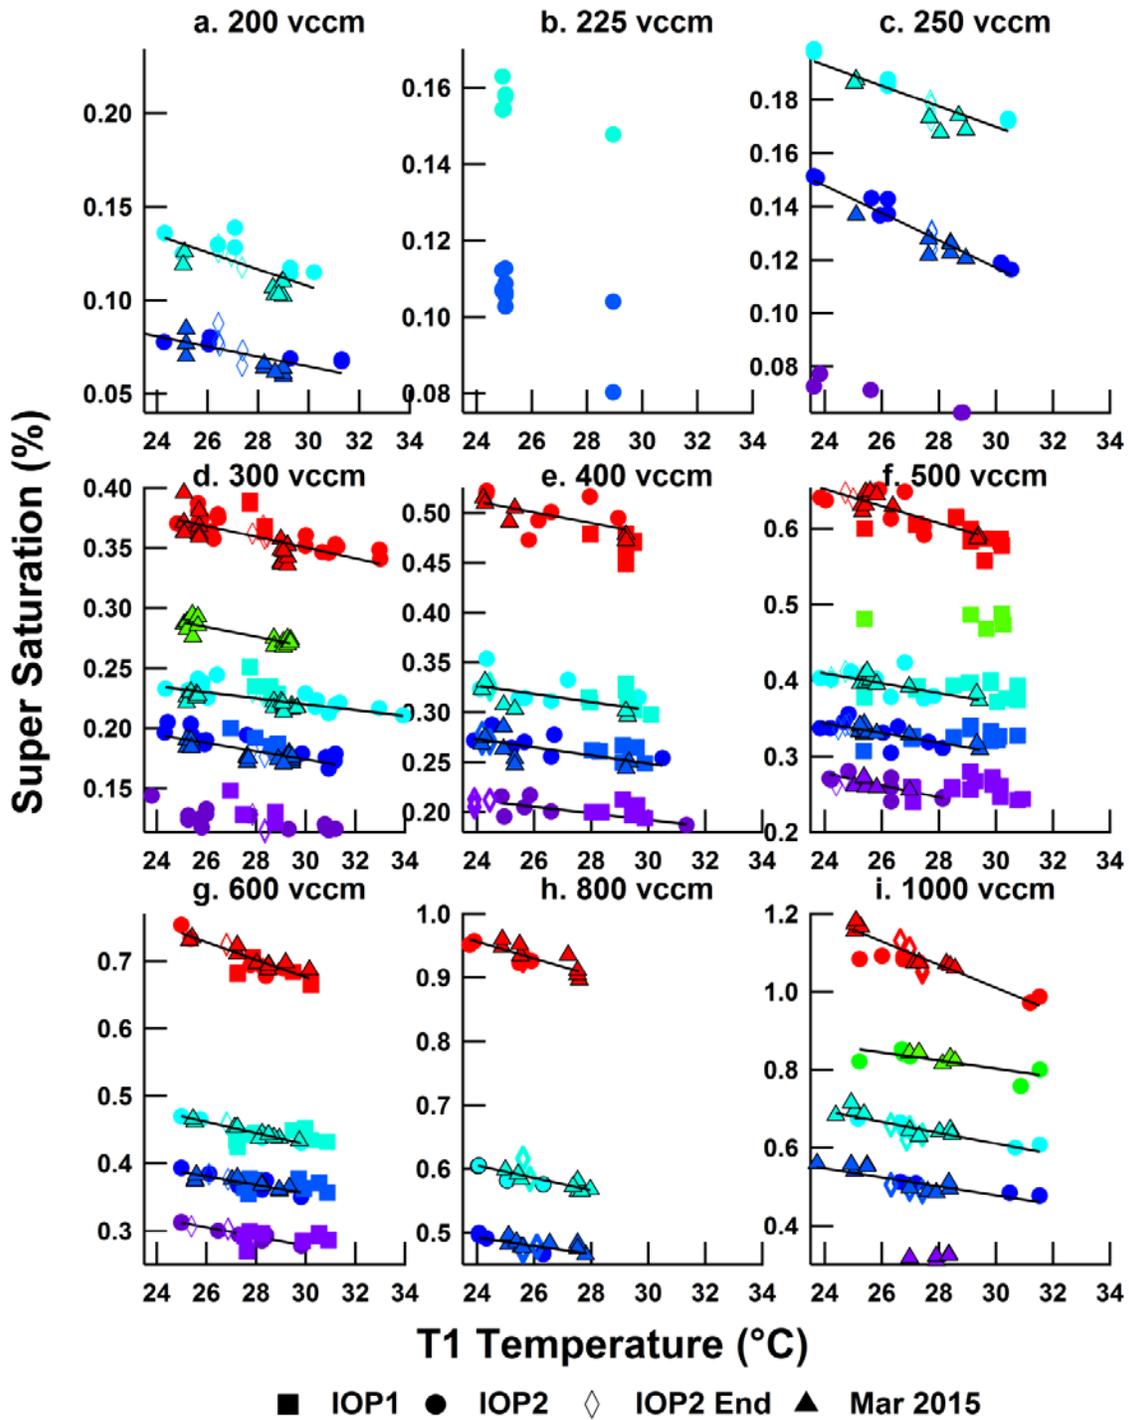

52

53 Figure S2: Instrument operation sequence showing set points of DMA classified particle
 54 diameter, Q_{CCN} and ΔT for one full measurement cycle. Red vertical lines mark the start and
 55 finish of one cycle.

56

57 Figure S3: Calibrated CCN counter supersaturation as a function of ΔT at T_1 of 25°C for Q_{CCN}
 58 ranging from 0.2 to 1.0 LPM.

59

60 Figure S4: Calibrated instrument supersaturation as a function of T_1 for different ΔT and Q_{CCN}
 61 values. The symbol colors of purple, dark blue, light blue, green and red correspond to ΔT values
 62 of 4.5, 5.5, 6.5, 8.0, and 10.0°C, respectively. Calibrations were carried out throughout the entire
 63 campaign (February/March 2014 - ■; August 2014 - ●; October 2014 - ◇; March 2015 - ▲). The
 64 lines represent least square fits of the calibration results.

65 **2 ARM Facility Instruments**

66 **2.1 Measurements of Oxides of Nitrogen**

67 Oxides of nitrogen were measured by catalytic conversion to NO and chemiluminescence at
68 one minute time resolution. The NO/NO₂/NO_y system is based on two Thermo Scientific 43i
69 instruments and customized by Air Quality Design, Inc. (Wheatridge, CO) for detection of NO.
70 The inlet/converter box is external and located at 10 meters above ground level and is
71 environmentally controlled. A dedicated channel converts total NO_y (NO + NO₂ + HNO₃ +
72 peroxy acyl nitrates + aerosol nitrates, but not NH₄) to NO via a Mo catalyst heated to 325°C. A
73 second channel converts NO₂ to NO by a light emitting diode (LED) photolysis cell with 50%
74 conversion efficiency (C.E.). The LED is toggled on and off on a two minute cycle to measure
75 ambient NO and NO + C.E.× NO₂, and the NO₂ mixing ratio is derived from the difference of
76 the measurements. The inlet box contains mass flow controllers (MFCs) so that the residence
77 time to the chemiluminescence cells is minimal and occurs at reduced pressure. The unit is
78 calibrated daily with standard additions of NO and NO₂ to measure the conversion efficiency of
79 both the Mo converter (1.00±0.02) and the photolysis cell.

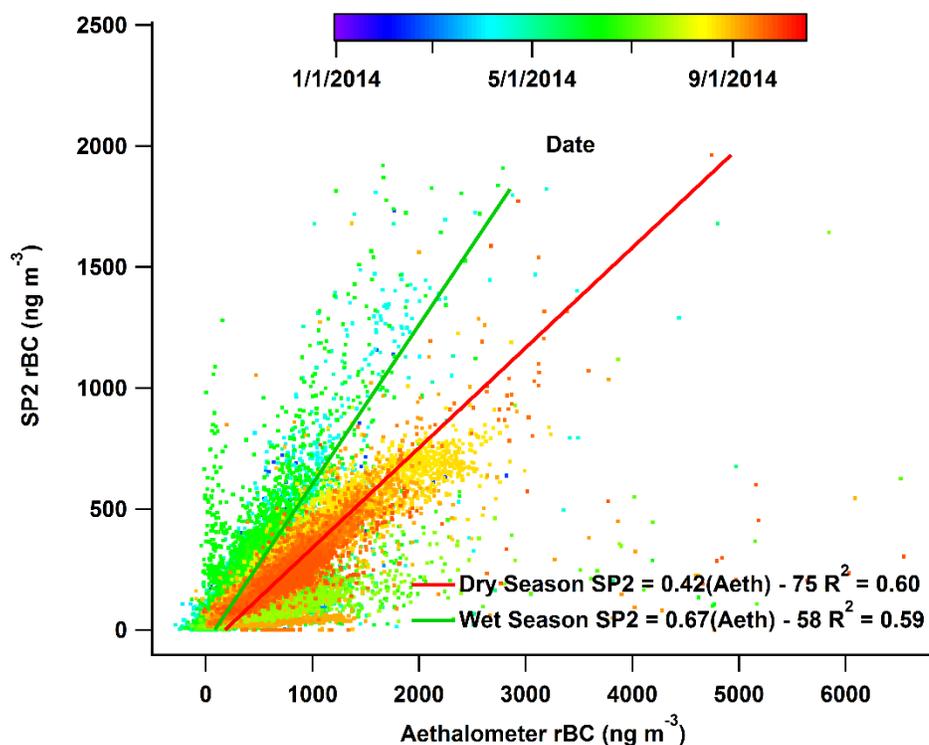

80 **2.2 Refractory Black Carbon Measurements**

81 The incandescence signal measured by SP2 is proportional to the mass of rBC in the particles
82 irrespective of whether the rBC is coated or not (Moteki et al., 2007; Schwarz et al., 2010;
83 Stephens et al., 2003). The SP2 was calibrated using size-selected fullerene soot with no
84 corrections for non-rBC content. The detectable size range of the SP2 is 75 – 600 nm (volume
85 equivalent diameter), which typically provides a direct measurement of > 90% of rBC mass
86 concentrations. If necessary, the complete mass size distribution is extrapolated to include rBC
87 outside of this size range assuming a log-normal distribution (Mei et al., 2013a). During

88 GoAmazon 2014/5, rBC mass was mostly within the detectable range. In contrast to the SP2, the
89 seven-wavelength Aethalometer (Arnott et al., 2005; Hansen et al., 1984) reports an equivalent
90 black carbon mass loading by converting a light absorption measurement from aerosols
91 accumulated on a filter relative to a manufacturer-supplied conversion. However, there is
92 substantial and growing evidence relating to measurement artifacts attributed to aerosol loading
93 effects and enhanced light absorption through multiple-scattering of photons (Collaud Coen et
94 al., 2010; Rizzo et al., 2011; Schmid et al., 2006; Virkkula et al., 2015; Virkkula et al., 2007;
95 Weingartner et al., 2003). Given the more complete dataset of the Aethalometer, our analysis
96 utilized the Aethalometer data only when SP2 data was unavailable. The available concurrent
97 SP2 and Aethalometer datasets were used to derive a linear relationship to correct for
98 Aethalometer measurement artifacts cited above. The mass concentrations of refractory black
99 carbon (rBC) derived from SP2 and Aethalometer data were averaged to a common time base
100 and the least square linear fit between both rBC mass concentrations is shown in Fig. S5 for both
101 the wet and dry seasons. The linear relationship exhibited a seasonal dependence, which might
102 be driven by variations in RH, the ratio of mass concentrations of organics to BC, or a
103 combination of both. The rBC mass concentration derived from the Aethalometer measurement
104 was used to fill the gaps in the SP2 data after scaled using the linear relationship corresponding
105 to the respective season.

106

107

108

109 Figure S5: Correlation between rBC mass concentrations derived from the Aethalometer and SP2
 110 measurements. Data points are colored by the time of the measurements. The red and green lines
 111 represent least square fit of data collected during the dry and wet seasons, respectively.

112

113 3 Reduction of the size resolved CCN activation spectrum

114 3.1 Correction for multiple charging

115 Size-resolved CCN activation fraction was characterized at particle diameters of 51, 75, 94,
 116 112, 142, 171 and 222 nm. These sampling sizes were selected to form a progression of particle
 117 diameters corresponding to doubly and triply charged particles (e.g. 112 nm corresponds to the
 118 diameter of doubly charged particles, when the DMA is set to select particles with a diameter of
 119 75 nm. See Table S1 for more details). The contribution of doubly and triply charged particles to
 120 the activation fraction was corrected using the size distribution measured by the SMPS (Model
 121 3080 TSI, Inc) in MAOS and particle charging probabilities (Wiedensohler, 1988). In cases
 122 when the size distribution data were not available, we used the concentrations of classified

123 particles measured by the CPC in the size-resolved CCN system when sampling at corresponding
124 multiple-charged sizes. The impact of multiple-charged particles on activation fraction was then
125 accounted for using the concentration of multiple-charged particles and the measured activation
126 fractions at the corresponding sizes. This is similar to the methods established in the literature
127 (Rose et al., 2008). When direct measurements of the activation fraction of multiple charged
128 particles were not available, the multiple charged particles were assumed to have the same
129 distribution of κ as the singly charge particles, and the activation fraction was corrected using the
130 following iterative approach. First, the activation fractions of multiple charged particles were
131 derived from the measured activation fractions, taken into consideration the same κ distribution
132 but larger particle diameters. These derived activation fractions at multiple charged sizes were
133 then used to correct measured activation fraction using the approach described above. This
134 process was continued until the corrected activation fraction of singly charged particles
135 converged.

136

137 **3.2 Data quality control criteria**

138 Several quality-control criteria were applied to the data and results from the fitting of
139 activation spectrum. The measurement of the entire activation spectrum at a single particle
140 diameter took about 5-20 minutes. Individual points (i.e., activation fraction at a single S) of an
141 activation spectrum were excluded from the fitting if the standard deviation of 1-sec
142 measurements of the classified particle concentration is greater than 30% of the mean value for
143 the current size, or single data points are more than 1.5 times the mean. This is to remove large
144 fluctuation or spikes in CPC concentration due to contamination by emission of site generator or
145 traffic. The removal of measurement at single supersaturation typically does not prevent fitting

146 of the activation spectrum using data at remaining supersaturation points. Parameters derived
147 from the fitting of activation spectrum were flagged and excluded from further analysis in this
148 study for the following scenarios:

- 149 1. The fitted S^* is outside the supersaturation range of the measured activation spectrum.
- 150 2. The fitted maximum activated fraction (E) is not within 15% of any activated fraction
151 measured at the three highest supersaturations. This indicates that the activation fraction
152 did not reach a plateau even at the highest supersaturations sampled, and therefore E is
153 not well constrained by the activation spectrum.
- 154 3. The residue of the fit is greater than 0.1. This indicates relatively poor fit, which
155 represented less 1% of the activation spectra.
- 156 4. The fitted E is less than 0.5, indicating external mixtures with substantial fraction of fresh
157 black carbon and primary organic aerosols emitted by the generator, vehicles, and grass
158 cutting activities at or near the site.

159 For the one-year measurement period, 6.5 % of the total activation curves were removed by
160 the above data quality filters.

161

162 **3.4 Deriving average particle hygroscopicity and hygroscopicity dispersion from activation** 163 **spectrum**

164 For particles with the same size and composition (i.e., hygroscopicity), a step increase of R_a
165 from 0% to 100% with increasing supersaturation is expected because all particles would have
166 the identical critical supersaturation (S_c). The measurements of ambient aerosols show more
167 gradual increase in R_a (i.e., instead of a step change), suggesting heterogeneity in particle S_c . The
168 heterogeneity in particle S_c , as described by σ_s , is due to a combination of width of DMA transfer

169 function (particles classified by a DMA do not have exactly the same size), instrument non-
 170 idealities, and the heterogeneity in particle hygroscopicity. The value of σ_s due to the
 171 heterogeneity in particle hygroscopicity alone can be estimated by:

$$172 \quad \sigma_s = \sqrt{\sigma_{s,m}^2 - \sigma_{s,AS}^2} \quad (S1)$$

173 Where $\sigma_{s,m}$ and $\sigma_{s,AS}$ are the values corresponding to the ambient measurement and the calibration
 174 using ammonium sulfate, respectively. Particle critical supersaturation S_c is related to
 175 hygroscopicity κ by (Petters and Kreidenweis, 2007):

$$176 \quad S_c(\kappa) = \left(\frac{4A^3}{27D_p^3\kappa} \right)^{1/2}, \quad (S2)$$

$$A = \frac{4\sigma_w M_w}{RT\rho_w}$$

177 Where D_p is the particle diameter, M_w , ρ_w and σ_w are the molecular weight, density and surface
 178 tension of water, respectively. The probability distribution function of particle hygroscopicity
 179 $p(\kappa)$ can be derived as the following:

$$180 \quad p(\kappa) = -\frac{dR_a(S_c(\kappa))}{d\kappa} \quad (S3)$$

181 Where R_a is the fitted active spectrum with σ_s adjusted using Eq. (S1). The dispersion of κ , which
 182 describes the heterogeneity of hygroscopicity for activated particles, is given by (Mei et al.,
 183 2013):

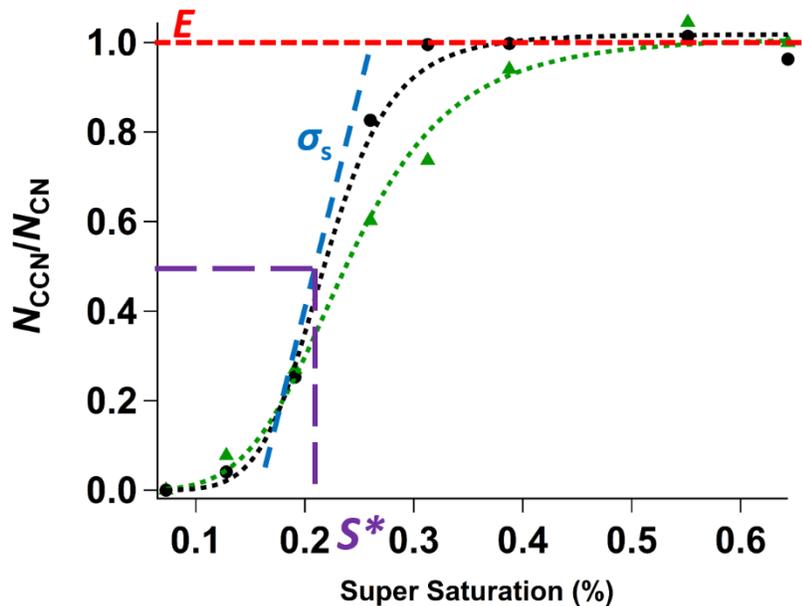

$$184 \quad \sigma(\kappa) / \overline{\kappa_{CCN}} = \left[\exp(4\sigma_s^2) - 1 \right]^{1/2} \quad (S4)$$

185 where $\sigma(\kappa)$ and $\overline{\kappa_{\text{CCN}}}$ are the standard deviation and average value of the hygroscopicity for
186 activated particles.

187 It is worth noting that because of the skewness of the lognormal distribution, the average particle
188 hygroscopicity $\overline{\kappa_{\text{CCN}}}$ is higher than κ^* , which corresponds to the fitted S^* , and represents the
189 median hygroscopicity of activated particles (Fig. S6). The difference between $\overline{\kappa_{\text{CCN}}}$ and κ^*
190 becomes significant at high σ_s values (Fig. S7). In this study, $\overline{\kappa_{\text{CCN}}}$ is derived from the
191 probability density function using the following equation:

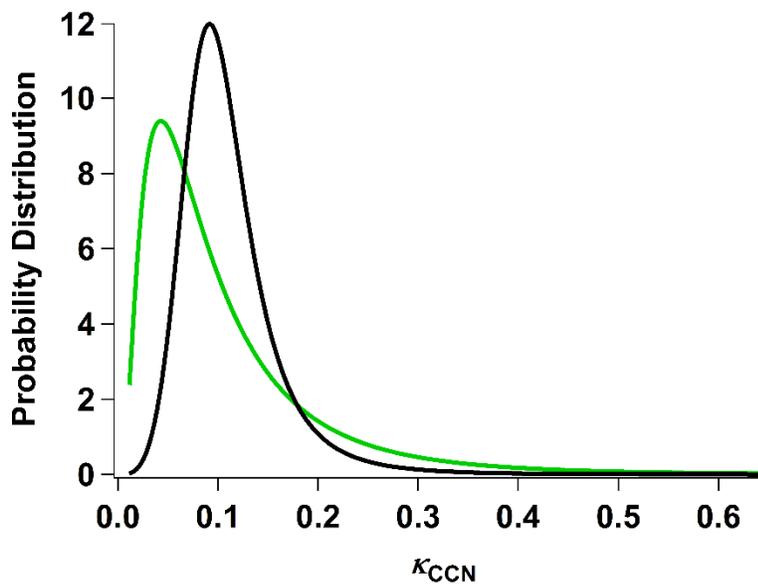

$$192 \quad \overline{\kappa_{\text{CCN}}} = \frac{\int_0^{0.65} \kappa \cdot p(\kappa) d\kappa}{\int_0^{0.65} p(\kappa) d\kappa} \quad (\text{S5})$$

193 The upper limit of the integration is limited to 0.65, which reflects the maximum particle
194 hygroscopicity expected at the T3 site. The organic hygroscopicity is derived from the average
195 particle hygroscopicity $\overline{\kappa_{\text{CCN}}}$ and average chemical composition.

196

197 Figure S6: Sample activation spectra for particles with diameter of 142 nm. The black dots and
 198 green triangles represent spectra with a low dispersion ($\sigma_s = 0.2$; $\sigma(\kappa)/\overline{\kappa_{\text{CCN}}} = 0.4$) and a much
 199 higher dispersion ($\sigma_s = 0.4$; $\sigma(\kappa)/\overline{\kappa_{\text{CCN}}} = 0.9$), respectively.

200

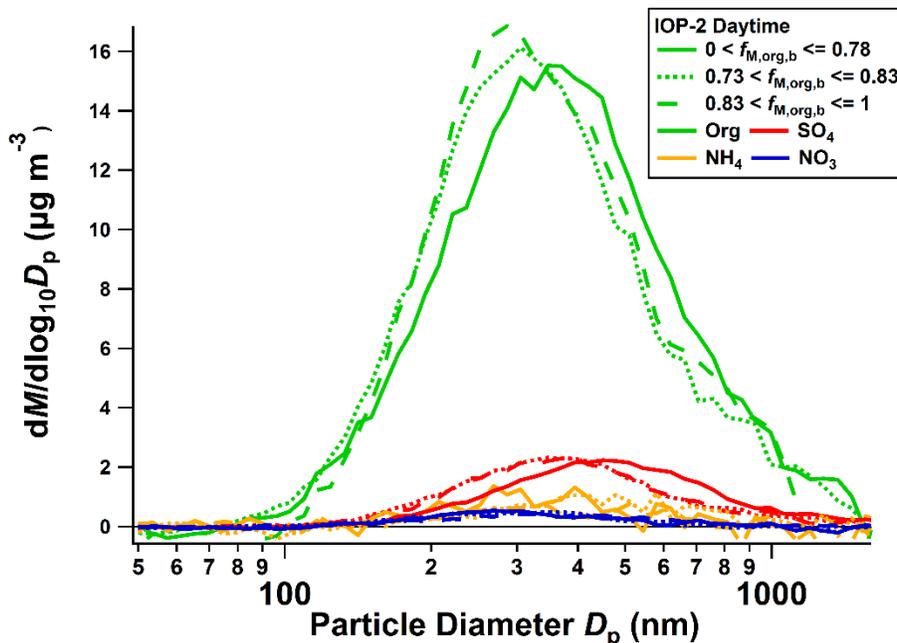

201 Figure S7: Probability density distributions of particle hygroscopicity derived from the fitted
 202 activation spectra shown in Figure S6. As dispersion increases, the distribution becomes
 203 increasingly asymmetric, and the difference between $\overline{\kappa_{\text{CCN}}}$ and κ^* increases.

204 **4 Aerosol composition derived from AMS and rBC measurements**

205 **4.1 Bulk and size-resolved mass concentration of aerosol species**

206 Given the very low aerosol mass concentration in the Amazon basin, the signal to noise ratio
207 of particle time-of-flight (P-ToF) mode measurement was not sufficient to directly provide size
208 resolved species mass concentrations for individual CCN activation spectrum. Instead, the size
209 resolved species mass concentrations were constructed by combining the bulk mass concentrations
210 measured in MS mode, which have higher signal to noise ratio, and P-ToF mode size resolved
211 species mass distributions averaged over extended time periods. For both IOPs, the bulk organics
212 mass fraction was derived from MS mode portion of individual AMS measurement. Based on the
213 bulk organic mass fraction, measurements during IOP1 were then classified into three groups
214 with equal number of measurements, and the characteristic mass size distribution of each species
215 (i.e., organics, SO₄, NO₃, and NH₄) was averaged from P-ToF measurements within each group.
216 For IOP2, the measurements were classified into three groups each for day and night periods
217 based on the bulk aerosol organic mass fraction, and the mass size distribution of each species
218 was averaged from P-ToF measurements in each of the six groups. The average mass size
219 distributions of the four species for the three groups during the daytime of IOP2 are shown in
220 Fig. S8 as examples. The underlying assumption is that observed aerosols exhibiting similar
221 bulk composition (i.e., organic mass fraction) during the IOPs also had species mass size
222 distributions with the same shapes. The vacuum aerodynamic diameter (D_{va}) measured by the
223 AMS was converted to particle mobility diameter (D_m) and volume equivalent diameter (D_v)
224 using the particle density with the assumption of spherical particles, which is reasonable given
225 most of the aerosol observed at T3 site were quite aged. The average densities were calculated
226 using the approach described in Kuwata et al. (2012), and were 1.45 $\mu\text{g m}^{-3}$ and 1.47 during IOP
227 1 and 2, respectively. In this study, unless otherwise indicated, particle diameter D_p represents

228 the mobility diameter (D_m), which is equivalent to the volume average diameter given the
 229 assumption of spherical particles.

230
 231 Figure S8: Size resolved mass concentrations of organics, SO_4 , NO_3 , and NH_4 averaged from P-
 232 ToF measurements for each of three groups during the day time of IOP2 (dry season). The three
 233 groups were classified based on bulk organics mass fraction ($f_{M,\text{org}}$).

234
 235 For individual AMS measurements, the size resolve chemical composition was then
 236 derived as follows: the organic mass concentration at the particle diameter of CCN
 237 measurements, $m_{\text{org}}(D_p)$, was calculated as:

$$238 \quad m_{\text{org}}(D_p) = M_{\text{org},b} \times \frac{\bar{m}_{\text{org}}(D_p)}{\int_{D_{p,\min}}^{D_{p,\max}} \bar{m}_{\text{org}}(D'_p) d \log D'_p} \quad (\text{S6})$$

239 where $M_{\text{org},b}$ is the bulk organic mass concentration from MS mode measurement, $\bar{m}_{\text{org}}(D_p)$ is
 240 the average organic mass size distribution with respect to $\log D_p$, $D_{p,\max}$ and $D_{p,\min}$ are the

241 maximum and minimum diameters of the average mass size distribution. Using the same
 242 approach, the mass concentration of SO_4^{2-} , NO_3^- , and NH_4^+ at specific D_p are calculated using
 243 the corresponding average mass size distributions. Mass concentration for black carbon
 244 $m_{rBC}(D_p)$ is derived with the assumption that the mass size distribution of rBC has the same
 245 shape of the total mass size distribution:

$$246 \quad f_{M,rBC} = \frac{M_{rBC,b}}{M_{total,b}} = \frac{m_{rBC}(D_p)}{m_{\text{SO}_4^{2-}}(D_p) + m_{\text{NO}_3^-}(D_p) + m_{\text{NH}_4^+}(D_p) + m_{org}(D_p) + m_{rBC}(D_p)} \quad (S7)$$

247 where $f_{M,rBC}$ is the bulk mass fraction of refractory black carbon, $M_{rBC,b}$ and $M_{total,b}$ are the
 248 bulk rBC and total aerosol mass concentrations, respectively. From Eq. (S7), $m_{rBC}(D_p)$ can be
 249 derived as:

$$250 \quad m_{rBC}(D_p) = \frac{f_{M,rBC} \left[m_{\text{SO}_4^{2-}}(D_p) + m_{\text{NO}_3^-}(D_p) + m_{\text{NH}_4^+}(D_p) + m_{org}(D_p) \right]}{(1 - f_{M,rBC})} \quad (S8)$$

251 The fractional chemical composition at the size of CCN measurement D_p was then derived from
 252 the species mass concentrations calculated above. While not perfect, this approach allowed us to
 253 take both the temporal variation and size dependence of species mass concentrations into
 254 consideration when deriving particle composition at the sizes of CCN measurements. This is
 255 important because the organic volume fraction, required to derive the organic hygroscopicity was
 256 often much higher at the sizes of CCN measurements than that based on the bulk measurements.

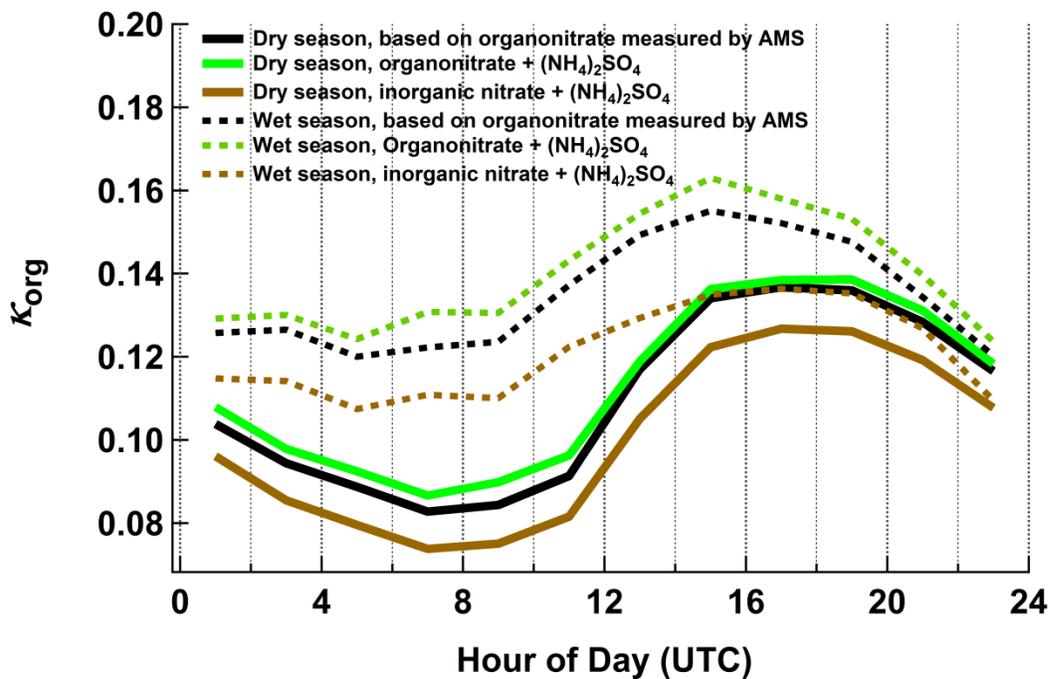

257

258

259 4.2 Sulfate and nitrate

260 Outside of the IOP periods, particle composition was derived from ACSM data, and the
261 retrieval of organonitrate mass concentration is not available. In addition, the detection limit of
262 NH_4^+ for the ACSM is very high, such that the measurement of NH_4^+ mass concentration was
263 too noisy for determining aerosol ionic balance. The sensitivity of derived κ_{org} to the assumption
264 on nitrate was examined using the AMS data from the two IOPs to inform the appropriate
265 assumptions for the analysis outside the IOP periods. Organic hygroscopicity was calculated
266 using three different approaches: (1) the approach based on the retrievals of both inorganic and
267 organic nitrate mass concentrations from AMS, as described in section 3.2 of the main text, (2)
268 all NO_3^- was assumed from NH_4NO_3 and all sulfate from ammonium sulfate, and (3) all NO_3^-
269 was from organonitrate with all sulfate from ammonium sulfate. κ_{org} derived using the three
270 different assumptions are shown in Figure S9 for both IOPs. When all NO_3^- is assumed from
271 organonitrate (i.e., approach 3), the derived κ_{org} values are very close to those based on retrieved
272 organonitrate and inorganic nitrate concentrations from AMS data (i.e., approach 1). As a result,
273 for measurements outside of the two IOPs when only ACSM measurements are available, all
274 measured NO_3^- was assumed from organonitrate and sulfate was assumed from ammonium
275 sulfate.

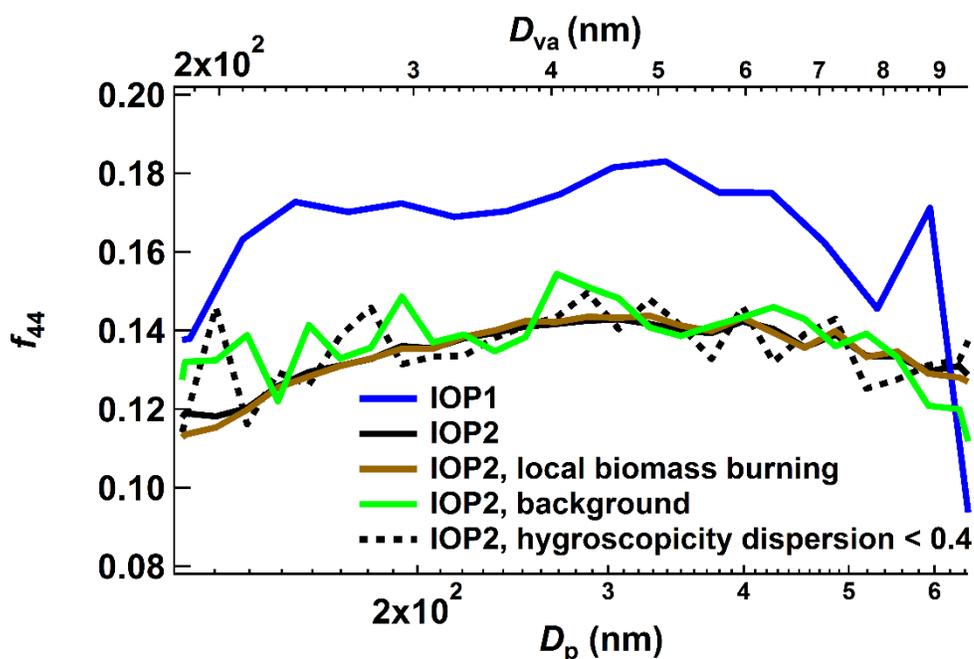

276

277

278 Figure S9: Diel variations of organic hygroscopicity derived using the three different
 279 assumptions on nitrate described in the text (i.e., mixed inorganic/organic nitrates, all organic
 280 nitrate, and all inorganic nitrate).

281

282

283 Figure S10: Size dependence of the fraction of the organic mass at $m/z = 44$ (f_{44}), which is
 284 indicative of the extent of oxidation. The f_{44} averaged during IOP1 was essentially independent
 285 of particle diameter D_p from 140 to 400 nm, a size range that dominated bulk organic mass
 286 concentration and encompasses the diameters of CCN measurements (i.e., 142 and 171 nm).
 287 During the IOP2, f_{44} averaged for all data and local biomass burning air mass type showed a clear
 288 dependence on D_p . In comparison, f_{44} averaged for the background condition and the periods
 289 with low hygroscopicity dispersion ($\sigma_{\bar{\kappa}}/\bar{\kappa} < 0.4$) during IOP2 had lower signal to noise ratio due
 290 to the low mass loading, but were largely independent of particle size.

291

292 **Tables**

293 Table S1: Particle diameter classified by the DMA and the corresponding diameters for doubly
 294 and triply charged particles. Diameters in the parenthesis represent the measurements (if
 295 available) used to correct the contribution of doubly and triply charged particles to the measured
 296 activation fractions.

DMA classified singly charged particles, D_p (nm)	Doubly charged particles D_p (nm)	Triply charged particles D_p (nm)
51	75 (75)	94 (94)
75	112 (112)	142 (142)

319

320 # An invalid fit of the CCN activation spectrum (Sec. S3.2)

321 \$ One or more of the measurements (CN, SMPS, CO, rBC) needed to classify air mass is missing
322 or air mass is not classified as one of the four types using the criteria described in Table S2.
