Interactive comment on “Variational estimates of black carbon emissions in the western United States” by Y. Mao et al.

Anonymous Referee #1
Received and published: 12 September 2014

The authors use a surface observations from the IMPROVE network and the chemical transport model GEOS-Chem and its adjoint to estimate concentrations of BC in the atmosphere in the Western U.S. during July-September of 2006.

The major finding is that the inversion system accurately predicts total emissions of BC, but cannot distinguish between different sources of BC. Adding additional ‘observations’ of biomass burning-derived BC leads to predictions of higher biomass burning and anthropogenic BC emissions. This result is not improved with additional surface observations of emissions.

I found the manuscript a little hard to read. The manuscript contains a lot of information (22 pages worth + figures). Improving tables 1 and 2, providing additional information about each ‘case’ in the figure headers would greatly improve clarity.

The manuscript should be shortened by streamlining the results and discussion section, and removing redundant findings/interpretation of findings. For example, the following statement is repeated multiple times: ‘This indicates that the inversion system lacks the ability to effectively distinguish collocated biomass burning and anthropogenic emissions in the WUS on model grid scales.’

I wonder if the manuscript could be restructured with a stronger emphasis on the results and then a list of reasons for the results rather than being taken step-by-step through a long list of modeling cases.

The manuscript can also be shortened considerably and made easier to follow by moving citations to the end of sentences, rather than starting a lot of sentences with ‘Example et al. (2006) showed . . .’. Please add a summarizing statement in the introduction and results/summary of how exactly this study differs from Mao et al. 2014. The information is in the text, but it is hard to find.

Title
The title does not convey the main message of the manuscript. I suggest changing the title to something like ‘large uncertainties remain in the magnitude and sources of black carbon emissions in the western United States’ or to make it more clear that ‘variational’ refers to a type of inversion modeling study.

Specific comment (incl. language)

Manuscript
Please use ‘variational’ or ‘adjoint’ throughout the manuscript; using both terms is confusing to readers not familiar with the inverse modeling methods.

Please use consistent spelling throughout the manuscript, including figures and tables.
for Western US or western US or WUS.
Remove spaces between numbers and % or degree signs.
Please spell out abbreviations, including BC if they occur at the beginning of sentences.
Please use italics for a priori and a posteriori – it would make it easier to identify the terms in the text.

Introduction
P21867 L4 [. . .] in the IPCC 2007` should be “two times larger than previous estimates (IPCC, 2007).” (please check the latest IPCC report for updates!)
P21867 L5-7 Remove ‘both’ in ‘also an important agent to both’ and remove ‘and cause global warming (IPCC, Bond)’ – this is repeating the previous statement.
P21867 L15 Change ‘the severest’ to ‘the most severe’ drought
P21867 L13-17 The sentences ‘In the western US . . .’ and ‘Recently, CA is experiencing . . .’ might wrongly suggest that the mountain snowpack in the Sierras is a dominant source of Colorado river water. Please rephrase.
P21867 L23-26 In ‘Long-term records . . .’ Increasing urbanization should be mentioned as another driver of fires in Southern California, not just climate change (which is also partially driven by the urban heat island effect), because most fires in CA are ignited by people.
P21868 L6-7 ‘Top-down inverse methods is’ - missing ‘The’ or change to ‘Top-down inverse modeling . . .’ More importantly, is it correct to use the term ‘top-down’ here, since the model is constrained with surface observations (bottom-up)? Maybe it would be more appropriate to just use the term ‘inverse’-modeling?
P21869 L6-14 Please shorten: Starting each sentence with the study author makes this list very wordy. I suggest listing the studies with the references in parentheses at the end of each type of study/model/region.
P21869 L15 The term ‘variational’ is introduced for ‘adjoint’, please move this to P21867 L9 when inversions are explained.
P21869 L20 ‘elevated mountainous’ makes no sense. Are these sites elevated in anything but relief?
P21869 L17 please remove ‘for clarity’
P21869 L20 ‘elevated mountainous’ makes no sense. Are these sites elevated in anything but relief?

Methods
P21870 L2 How can the update of seasonality in the data be from 2003 (Park) if the data is from 2007 (Bond)? Is Bond 2007 using the wrong seasonality?
P21870 L3 remove ‘emissions’ after (GFEDv2)
P21870 L12-13 I suggest removing this statement on the history of the adjoint.
P21870 L26 Why is delta sigma=0.1 used?
P21871 L2 Text uses ‘r’, but Figure 2 uses ‘R’ to describe correlations. Please use the same terminology in all instances.
P21871 L10 should read X [. . .] ARE the emissions (not IS)
P21872 L16-18 I suggest shortening to: We set the observation error at 30, 50, or 100%, which includes the model, representation, and measurement error.
P21873 L1-2 It is not clear from this statement whether scaling emission factors or emissions is the standard practice. Please rephrase.
P21873 L14-18 This can be shortened, to remove redundant information, to ‘Here we calculate cost function gradients with a hybrid form of scaling factors (Jiang et al.,
The assumption that a priori errors are spatially uncorrelated hinges on the consideration that the spatial resolution of the CTM is much larger than the correlation length scale of the individual emission sources (Henze et al., 2009).

Summary and Conclusions

It is not necessary to provide another summary. The main questions, activities and findings should be summarized ONLY in the abstract. Please shorten this section to less than 1/3 page of text, focusing on what next steps the work implies.

Tables

Table 1 This table is very hard to read, because there are 12 comments underneath the table, and e.g. ‘e’ refers to Case 1. From looking at a ‘Case x’ the reader cannot intuitively understand how the difference in the parameters affects the results.

It would be easier to understand the different set-ups if the authors added columns for the parameters that are changing: (1) the size of inversion (0.5x0.667 or 2x2.5 degree), (2) the number of IMPROVE sites used, (3) the uncertainty estimate for biomass burning, (4) the uncertainty estimate for anthropogenic emissions, (4) the observational error, and (5) the a priori biomass burning emissions. I also suggest to moving the ‘case’ column more to the left, next o ‘adjoint’.
In the adjoint, the uncertainty for biomass burning emissions is set to 500% (Case 1) and then 300% (Case 2), and then the uncertainty for anthropogenic emissions is 30% (Case 3) and then 200% (Case 4). I propose to change the order, so that the uncertainty either increases or declines for each parameter.

To the header, please add an explanation for ‘giga’ (Gg (10^9 g)).

Table 2 As for Table 1, it is hard to read this table because there is so much information in the comments under the table. It would help if any of the info could be transferred to the table. ‘A posteriori’ is kind of suspended between columns. Does this refer to inversions and ‘ghost’ emissions? The label should be moved into the same column as ‘a priori’. It is not clear from the header or comments what Delta Emissions and J(X) reduction are.

Figures

This paper has a lot of figures (15). I strongly encourage the authors to consider moving some of the figures to an online supplementing material. Which figures are critical to understanding the main findings?

Suggestions for moving to the appendix: Figure 2, Figure 3 & 4 (merged into a two panel figure)

Figure 1 ‘.’ missing after US (‘… western US Also…’) Please explain why solid circles differ in diameter.

Figure 2 What are the units of finite difference sensitivities; please add this information to the y-axis labels.

Figure 4 Text in caption does not match y-axis label. Please correct.

Figure 5, 6, 7, 10

Figures 5-7: I find it misleading that the same color is used to depict different magnitudes of change, e.g. for Fig. 5 in biomass burning vs. anthropogenic and total emissions.

Figure 5: Scale bars under the figure panels are bleeding into each other and some numbers/letters are cut in half. I suggest using only one scale bar for each column, shown at the bottom (or different colors for different magnitudes).

Figure 5-7, 9-10, 13 In caption, please briefly explain ‘Case’, so the reader does not have to refer back to Table 1 to understand the figure.

Figure 11 Caption mistake: the a priori, should be the a priori

Figure 15 Legend text is misaligned, please correct Taylor Scores.
