Abstract

To better understand the photochemical processing of dicarboxylic acids and related polar compounds, we conducted batch UV irradiation experiments on two types of aerosol samples collected from India, which represent anthropogenic (AA) and biogenic aerosols (BA), for time periods of 0.5 to 120 h. The irradiated samples were analyzed for molecular compositions of diacids, oxoacids and α-dicarbonyls. The results show that photochemical degradation of oxalic (C$_2$) and malonic (C$_3$) and other C$_8$-C$_{12}$ diacids overwhelmed their production in aqueous aerosols whereas succinic acid (C$_4$) and C$_5$-C$_7$ diacids showed a significant increase (ca. 10 times) during the course of irradiation experiments. The photochemical formation of oxoacids and α-dicarbonyls overwhelmed their degradation during the early stages of experiment, except for ω-oxooctanoic acid (ωC$_8$) that showed a similar pattern to that of C$_4$. We also found a gradual decrease in the relative abundance of C$_2$ to total diacids and an increase in the relative abundance of C$_4$ during prolonged experiment. Based on the changes in concentrations and mass ratios of selected species with the irradiation time, we hypothesize that iron-catalyzed photolysis of C$_2$ and C$_3$ diacids dominates their concentrations in Fe-rich atmospheric waters, whereas photochemical formation of C$_4$ diacid (via ωC$_8$) is enhanced with photochemical processing of aqueous aerosols in the atmosphere. This study demonstrates that the ambient aerosols contain abundant precursors that produce diacids, oxoacids and α-dicarbonyls, although some species such as oxalic acid decompose extensively during an early stage of photochemical processing.

1 Introduction

Dicarboxylic acids and related polar compounds constitute a significant fraction of water-soluble organic aerosols in the atmosphere (Kawamura and Sakaguchi, 1999; Pavuluri et al., 2010; Saxena and Hildemann, 1996). They have a potential contribution to the formation of cloud condensation nuclei (CCN) due to their water-soluble...
and hygroscopic properties (Giebl et al., 2002; Saxena and Hildemann, 1996). Thus diacids and related compounds have an impact on the indirect radiative forcing and hydrological cycle (Albrecht, 1989; Twomey, 1977). They also involve in a series of reactions occurring in gas phase, aerosols and atmospheric waters (Chebbi and Carlier, 1996; Wang et al., 2010b). Although diacids, oxoacids and α-dicarbonyls can be directly emitted into the atmosphere from incomplete combustion of fossil fuels (Kawamura and Kaplan, 1987) and biomass burning (Narukawa et al., 1999), they are mainly formed by secondary processes of volatile organic compounds of anthropogenic and biogenic origin (Kanakidou et al., 2005; Kawamura et al., 1996a; Kawamura and Sakaguchi, 1999). They are further subjected to photochemical oxidation during long-range transport; e.g., carbonyls to carboxylic acids (Tilgner and Herrmann, 2010) and breakdown of higher to lower diacids (Kawamura and Sakaguchi, 1999; Matsunaga et al., 1999; Wang et al., 2010a).

Molecular distributions of diacids in atmospheric aerosols have generally been reported with a predominance of oxalic (C$_2$) acid followed by malonic (C$_3$) or succinic (C$_4$) acid in different environments (Kawamura and Kaplan, 1987; Kawamura and Ikushima, 1993; Kawamura and Sakaguchi, 1999; Narukawa et al., 1999; Pavuluri et al., 2010). The predominance of C$_2$ in different environments is likely explained because it is an ultimate end product in the chain reactions of diacids and various precursors including aromatic hydrocarbons, isoprene, alkenes and α-dicarbonyls (Carlton et al., 2007; Charbouillot et al., 2012; Ervens et al., 2004b; Kawamura et al., 1996a; Lim et al., 2005; Warneck, 2003). In contrast, C$_4$ was reported to be more abundant than C$_2$ in some aerosol samples collected from Antarctica (Kawamura et al., 1996b), the Arctic (Kawamura et al., 2010) and over the Arctic Ocean (Kawamura et al., 2012) as well as in ice core samples from Greenland (Kawamura et al., 2001). In addition, a significant reduction in C$_2$ diacid concentration and an inverse relationship between C$_2$ and Fe has been reported in stratocumulus clouds over the northeastern Pacific Ocean (Sorooshian et al., 2013). The predominance of C$_4$ over C$_2$ in ice core samples and atmospheric aerosols from polar regions, particularly in the Arctic marine aerosol sam-
ples collected under overcast conditions with fog or brume event (Kawamura et al., 2012) and the reduction of C\textsubscript{2} in cloud water, suggest that photochemical formation of C\textsubscript{4} and/or degradation of C\textsubscript{2} (Pavuluri and Kawamura, 2012) should be enhanced in atmospheric waters.

However, the photochemical formation and degradation of diacids and related compounds are not fully understood, particularly in aqueous phase because the composition of aqueous solutions used in laboratory experiments do not reflect the complex mixture of organic and inorganic aerosol constituents in the atmosphere and the experimental conditions are not necessarily atmospherically relevant (Ervens et al., 2011). Hence, it is required to investigate the fate of diacids and related polar compounds with photochemical processing in atmospheric waters. In this study, we conducted a laboratory experiment using two types of ambient aerosol samples collected from Chennai, India, which represent anthropogenic (AA) and biogenic aerosols (BA). The samples were exposed to UV irradiation in the presence of moisture for different time ranging from 0.5 to 120 h and then analyzed for diacids, oxoacids and α-dicarbonyls. Here, we report their molecular compositions and discuss the photochemical formation and/or degradation of diacids as a function of the irradiation time. Based on the results obtained, we propose possible photochemical formation and degradation pathways of diacids and related compounds with atmospheric implications.

2 Materials and methods

2.1 Atmospheric aerosol samples

In this study, we used two types of atmospheric aerosol (PM\textsubscript{10}) samples that were collected in winter on 28 January (IND104) and in summer on 25 May (IND178), 2007 during daytime (ca. 06:00–18:00 LT) from Chennai (13.03° N; 80.17° E), India using a high volume air sampler and pre-combusted (450°C, 4 h) quartz fiber filters. Sampling was conducted on the rooftop of the Mechanical Sciences building (∼ 18 m a.g.l.)
(above the ground level)) at the Indian Institute of Technology Madras (IITM) campus. The details of sampling site and meteorology are described elsewhere (Pavuluri et al., 2010). The sample filter was placed in a preheated glass jar with a Teflon-lined screw cap and stored in darkness at −20 °C prior to the experiment. Figure 1 presents ten-day backward air mass trajectories arriving in Chennai at 500 m.a.g.l. for every 6 h during the sampling periods of IND104 and IND178. Table 1 shows concentrations of elemental carbon (EC), organic carbon (OC), levoglucosan and sums of hopanes (specific biomarkers of petroleum and coal) and lipid class compounds: fatty acids and fatty alcohols, in IND104 and IND178 (Fu et al., 2010; Pavuluri et al., 2011).

The air mass trajectories showed that the air masses for the IND104 sample originated from the north Indian subcontinent passing over the Bay of Bengal (Fig. 1). In North India, anthropogenic emissions are mainly derived from fossil fuel combustion and forest fires (Lelieveld et al., 2001; Reddy and Venkataraman, 2002a). This sample is enriched with EC (Table 1). The anthropogenic signature of IND104 is further supported by high abundances of hopanes. In contrast, the air masses for the IND178 sample originated from the Arabian Sea passing over the south Indian subcontinent (Fig. 1), where the emissions from marine biota, combustion of biofuels (e.g., cow-dung) (Reddy and Venkataraman, 2002b) and livestock (Garg et al., 2001) are important. In addition, emission of volatile organic compounds (VOCs) from tropical plant species in India is enhanced in summer (Padhy and Varshney, 2005). This sample is enriched with OC but EC is less abundant (Table 1). The biogenic signature of IND178 is supported by high abundances of fatty acids and fatty alcohols (Table 1). Hence, we consider that IND104 represents anthropogenic aerosols (AA) whereas IND178 represents biogenic aerosols (BA).

2.2 Determination of trace elements, metals and water-soluble iron species

Trace elements and metals were determined using an inductively coupled plasma mass spectrometry (ICP-MS, Thermo Electron X Series) after the acid microwave digestion of samples (a filter disc of 1.8 cm in diameter) as reported by Theodosi et al. (2010b).
Recoveries obtained with the use of certified reference materials ranged from 90.0 to 104.1%. Water-soluble iron (Fe$_{WS}$: sum of Fe$^{2+}$ and Fe$^{3+}$ species) was determined spectrometrically using the Ferrozine colorimetric method developed by Stooky (1970) as reported by Theodosi et al. (2010a). Fe$^{2+}$ was measured using the same procedure without adding the reducing agent (hydroxylamine hydrochloride), and then Fe$^{3+}$ was estimated indirectly as the difference between Fe$_{WS}$ and Fe$^{2+}$. The recovery was $\sim 98.3\%$ for both Fe$_{WS}$ and Fe$^{2+}$.

2.3 Irradiation experiment of aerosol samples

Batch UV irradiation experiments using two aerosol samples (AA and BA) were conducted separately for 0.5, 1.5, 3.0, 6.0, 12, 18, 24, 36, 48, 72, 96 and 120 h. In each experiment, $\sim 12\,\text{cm}^2$ (ca. $3\,\text{cm} \times 4\,\text{cm}$) of sample filter was cut into 3~4 pieces and placed vertically in a cleaned quartz reaction vessel (cylinder, 100 mL) with the sample surface facing to UV light as depicted in Fig. 2. The sample was wetted by injecting $\sim 0.4\,\text{mL}$ of ultra pure organic free Milli Q water and sealed with Teflon-lined screw cap under the ambient pressure and then irradiated with a low-pressure mercury lamp (Ushio, UL0-6DQ) that emits a UV, whose spectra are characterized by main peak at 254 nm and minor peak at 185 nm as well as broad peak at $>254$ nm. The experimental setup (Fig. 2) was covered with a cartoon box containing a hole on each side for the passage of ambient air, and placed in a draft chamber. The temperature around the experimental system (i.e. inside cartoon box) was equivalent to room temperature ($25 \pm 1^\circ\text{C}$).

The main objective of UV irradiation with a wavelength primarily at 254 nm, rather than a solar spectrum, was to produce significant amount of hydroxyl radicals (•OH) from various sources described below that should be sufficient enough to act as the main oxidant in our experimental system. Although we do not preclude a minor photolysis of some organic compounds present in the aerosol samples by irradiation at $\leq 254$ nm, it is well established that low molecular weight diacids, oxoacids and $\alpha$-dicarbonyls have negligible absorbance at 254 nm and exhibit minimal photolysis (Carl-
Formation and degradation of diacids and related polar compounds
C. M. Pavuluri et al.

The irradiation of wetted aerosol sample at 254 nm induces the formation of O₃ from the dissolved O₂ followed by generation of H₂O₂, and direct photolysis of H₂O, NO₃⁻, NO₂⁻, H₂O₂, Fe(OH)²⁺ and certain organic compounds, and Fenton’s reaction of photochemically formed Fe²⁺ and H₂O₂ to produce •OH in aqueous phase (Arakaki and Faust, 1998; Carlton et al., 2006; Yang et al., 2008a). In fact, high amount of Fe, including water-soluble Fe²⁺ and Fe³⁺ species, is available in both AA and BA samples (Table 1), which could promote the Fenton’s reaction upon UV irradiation. In addition, O₃, H₂O₂, HOO• and NO₂ formed in aqueous phase reactions may be partitioned into gas phase and generate the gaseous •OH that should be re-partitioned into aqueous phase (Arakaki and Faust, 1998). These sources of •OH are similar to those of atmospheric waters: (i) gas/drop partitioning of •OH and (ii) gas/drop partitioning of O₃ followed by reaction with peroxo radical (HOO•), (iii) direct photolysis of H₂O, NO₃⁻, NO₂⁻, H₂O₂, Fe(OH)²⁺ and certain organic compounds, and (iv) Fenton’s reaction of Fe²⁺ and H₂O₂ (Arakaki and Faust, 1998).

Unfortunately, we could not approximate the actual concentrations of •OH in our experiments because we did not add any chemical (e.g., a standard compound whose kinetics are known) in order to keep our experimental system as realistic as possible. Furthermore, the formation of O₃ from the initially available O₂ (∼ 0.94 mM) in the reaction vessel may not cause the deficit of the O₂ that could potentially induce the polymerization of organics during the irradiation on aerosols for several hours, because the
additional \( \text{O}_2 \) could be produced from the gaseous \( \text{HOO}^* \) formed by direct photolysis of organics and Fenton’s reaction (Arakaki and Faust, 1998) during the experiment.

### 2.4 Measurements of diacids, oxoacids and \( \alpha \)-dicarbonyls

Immediately after the irradiation, samples were analyzed for diacids, oxoacids and \( \alpha \)-dicarbonyls using a method reported elsewhere (Kawamura, 1993; Kawamura and Ikushima, 1993). Briefly, the irradiated sample filter was extracted with Milli-Q water (10 mL \( \times \) 3) under ultrasound for 10 min and the extracts were concentrated to near dryness using a rotary evaporator under vacuum. The extracts were then derivatized with 14 % BF\(_3\)/n-butanol at 100 °C to butyl esters and/or butoxy acetals. Both the esters and acetics were extracted with \( n \)-hexane and then determined using a capillary GC (HP 6890) and GC-MS (Thermo Trace MS). Recoveries of authentic standards spiked to a pre-combusted quartz fiber filter were 73 % for oxalic (C\(_2\)) acid and more than 84 % for malonic (C\(_3\)), succinic (C\(_4\)) and adipic (C\(_6\)) acids (Pavuluri et al., 2010). The analytical errors in duplicate analysis of the aerosol filter sample are within 9 % for major species. Gas chromatogram of the field and laboratory blanks showed small peaks for C\(_2\), phthalic (Ph) and glyoxylic acids. Concentrations of all the species reported here are corrected for the non-irradiated field blanks (Pavuluri et al., 2010).

### 2.5 Quality control

To examine the possible experimental errors, we conducted replicate experiments (\( n = 3 \)) for 18 h irradiation of AA sample because potential variance in chemical composition of aerosol at different parts of the single filter, size of the filter sample used (i.e., amount of aerosols) and the amount of Milli Q water added could cause a deviation in the results of the irradiation experiment. The experimental errors, including the analytical errors, were found to be within 11 % for major species, except for C\(_3\) diacid (19 %). In addition, two irradiation experiments were conducted to check the procedural blank by using a clean quartz filter for 1.5 and 6.0 h. No peaks were detected, except for...
a small peak for C₂ and Ph. These results indicate that the occurrence of bias during the experiment is insignificant.

3 Results and discussion

3.1 Concentrations of trace elements, metals and water-soluble iron species

Concentrations of trace elements, metals and water-soluble Fe species (Fe²⁺ and Fe³⁺) determined in non-irradiated AA and BA samples are presented in Table 1. The trace elements and metals in AA sample, which mainly originate from soil dust (e.g., P, Al, Ca and Fe), non-ferrous metallurgical industrial activities (Cd, Cu and Zn) and fossil fuel combustion (Cr, Pb and V) (Mahowald et al., 2008; Pacyna and Pacyna, 2001), are significantly more abundant than in BA (by up to several times higher), except for S, Ni and Sb (Table 1). The high abundances of trace metals in AA further suggest that the AA sample should contain high abundances of anthropogenic organic matter. The high abundances of S, Ni and Sb in BA than in AA may be due to high emissions of the S from intensive consumption of biofuels, particularly cow-dung that contains higher S content (Reddy and Venkataraman, 2002b), while Ni and Sb are from some specific industrial activities in southern India. Although water-soluble Fe²⁺ and Fe³⁺ species are abundant in both AA and BA, their concentrations in BA are 30–50 % higher than in AA (Table 1). Further the fraction of water-soluble Fe (Feₗₘ: sum of Fe²⁺ and Fe³⁺) in total particulate Fe (Feₜₒₜ) is 2.77 % in AA whereas it is 14.6 % in BA.

3.2 Molecular compositions of diacids, oxoacids and α-dicarbonyls

A homologous series of normal (C₂-C₁₂) and branched chain (iso C₄-C₆) saturated α,ω-diacids were detected in both non-irradiated and irradiated AA and BA samples as well as aliphatic unsaturated diacids such as maleic (M), fumaric (F), and methyl-maleic (mM) acids and aromatic diacids such as phthalic (Ph), isophthalic (i-Ph), and
terephthalic (t-Ph) acids. Diacids with an additional functional group, i.e., malic (hydroxysuccinic, hC$_4$), ketomalonic (kC$_3$), and 4-ketopimelic (kC$_7$) acids, were detected, together with ω-oxoacids (ωC$_2$-ωC$_9$), pyruvic acid (Pyr), and α-dicarbonyls, i.e., glyoxal (Gly) and methylglyoxal (MeGly). ωC$_6$ will not be reported here due to the overlapping peak on GC chromatogram.

Oxalic (C$_2$) acid was found as the most abundant diacid in non-irradiated samples (accounting for 54% of total diacids in AA and 53% in BA), followed by Ph (10%), C$_4$ (9%), C$_3$ (8%) and C$_9$ (4%) in AA and by malonic (C$_3$) (9%), C$_4$ (6%) and t-Ph (6%) acids in BA. Branched chain diacids were significantly lower than the corresponding normal structures in both samples. Glyoxylic (ωC$_2$) acid is the most abundant oxoacid, comprising 64 and 57% of total oxoacids in AA and BA, respectively, followed by Pyr (13%) and 4-oxobutanoic (ωC$_4$) acid (10%) in AA and ωC$_4$ (18%) and Pyr (13%) in BA. MeGly is more abundant than Gly in AA whereas their abundances are equivalent in BA.

### 3.3 Changes in concentrations of diacids and related compounds as a function of UV irradiation time

Changes in concentrations of individual and total diacids as a function of UV irradiation time in AA and BA are depicted in Fig. 3, while those of oxoacids and α-dicarbonyls as well as total oxoacids and α-dicarbonyls in Fig. 4. Concentrations of C$_2$ diacid were sharply decreased by a factor of 3–9 (from 553 to 61.7 ng m$^{-3}$ in AA and from 339 to 118 ng m$^{-3}$ in BA) within 6 and 12 h of UV irradiation, respectively (Fig. 3a). Then, the concentrations started to increase to maximize at 24 h (292 ng m$^{-3}$) in AA and 18 h (306 ng m$^{-3}$) in BA on further irradiation. They gradually decreased toward the end (120 h) of the experiment (Fig. 3a). Interestingly, C$_3$ diacid showed a temporal variation similar to C$_2$ in both AA and BA, except for few points (Fig. 3b). Relative abundances of C$_2$ in total diacids gradually decreased from non-irradiated samples (54% in AA and 53% in BA) toward the end (120 h) of the experiment (3.2% in AA and 9.2% in BA, Fig. 5).
Concentrations of $\omega$C$_2$, an immediate precursor of C$_2$ (Kawamura et al., 1996a; Lim et al., 2005; Warneck, 2003), increased with irradiation time up to 18 h in both AA and BA, except for two cases (3 and 6 h) of AA, and then gradually decreased until the end (120 h) of the experiment, except for one case (36 h) in AA (Fig. 4a). Pyr, Gly and MeGly, which are the precursors of $\omega$C$_2$ acid, are all produced by the oxidation of VOCs of anthropogenic and biogenic origin (Carlton et al., 2006; Ervens et al., 2004b; Lim et al., 2005; Warneck, 2003). They also increased with irradiation time up to 18 $\sim$ 24 h in both samples and then gradually decreased (except for MeGly in AA) until the end (120 h) of the experiment (Fig. 4g, i and j). However, the other precursor of C$_2$ diacid, kC$_3$ diacid (Kawamura et al., 1996a), showed a decrease with irradiation time throughout the experiment, except for few cases (Fig. 3v) whereas hC$_4$, a precursor of C$_3$ diacid (Kawamura et al., 1996a), increased up to 18 h in BA and 24 h in AA and remained relatively high until 72 h and then gradually decreased until the end (120 h) of the experiment (Fig. 3u).

In contrast, concentrations of C$_4$ diacid showed a gradual increase with irradiation time up to 72 h in BA and 96 h in AA followed by a slight decrease in the AA and a sharp decrease in BA (Fig. 3c). Relative abundance of C$_4$ diacid in total diacids also increased from 8.9 % (non-irradiated) to 82 % (120 h) in AA and from 6.4 to 88 % in BA (Fig. 5). Similarly, C$_5$ diacid in AA (Fig. 3d) showed a gradual increase with irradiation up to 36 h and stayed almost constant until 96 h followed by a slight decrease. Similar trend was found in BA (Fig. 3d). Both C$_6$ and C$_7$ diacids showed an increase with irradiation up to 6 $\sim$ 36 h and then a gradual decrease until the end (120 h) of the experiment (Fig. 3e and f). Concentrations of iC$_4$ diacid also increased with irradiation up to 18 h in BA and 36 h in AA and stayed relatively constant until 72 or 96 h. Then, the concentrations gradually decreased until the end (120 h) of the experiment (Fig. 3i). iC$_5$ and iC$_6$ diacids (Fig. 3 m and n) showed very similar trend with their corresponding normal diacids (Fig. 3d and e).

Long-chain (C$_8$–C$_{12}$) diacids showed a sharp decrease with irradiation up to 12 h and then a gradual decrease until the end (120 h) of the experiment (Fig. 3g–k). C$_8$, C$_9$ and
C_{12} diacids became below the detection limit within several hours, particularly in BA. On the other hand, unsaturated aliphatic (M, F, mM, and Ph) and aromatic diacids (i-Ph and t-Ph) showed a gradual decrease with irradiation, except for few cases during the early stages of the experiment (Fig. 3o–t). Concentrations of kC_{7} increased with irradiation time up to 18 h and then decreased gradually until 120 h (Fig. 3w) whereas oxoacids: ωC_{3}, ωC_{7} and ωC_{9} acids, showed a gradual decrease with irradiation, except for few cases (Fig. 4b, d and f). On the other hand, ωC_{4} acid showed a sharp increase up to 12 h and then a sharp decrease toward 24 h (Fig. 4c). Interestingly, temporal pattern of ωC_{8} acid (Fig. 4e) was similar to that of C_{4} diacid (Fig. 3c).

Thus the changes in the concentrations of individual diacids, oxoacids and α-dicarbonyls as well as relative abundances of individual diacids in total diacids and mass ratios of selected species in AA and BA found to be similar (Figs. 3–6), although significant differences are recognized between AA and BA samples during irradiation. Such similarities in the temporal variations of diacids and related polar compounds infer that their photochemical formation and degradation pathways in aqueous aerosols (Fig. 7) are almost same between anthropogenic and biogenic aerosols. However, there were significant differences in the rate of formation and/or degradation of diacids and related compounds between AA and BA, which might have been driven by the differences in the abundances of the diacids and related compounds as well as their precursor compounds in the original (non-irradiated) AA and BA samples. In fact, total diacids, oxoacids and α-dicarboxyls were higher in non-irradiated AA than in BA. On the contrary, OC that contains several precursor compounds (including fatty acids) of diacids and related polar compounds is higher in BA than in AA (Table 1).

### 3.4 Production and decomposition of short-chain diacids and related compounds

A sharp increase was observed in the concentrations of ωC_{2}, ωC_{4}, Pyr, Gly and MeGly with irradiation up to 18 ~ 24 h following a gradual decrease (Fig. 4), demonstrating an enhanced photochemical production of short-chain (≤C_{4}) oxoacids and α-dicarbonyls.
(Fig. 7) during an early stage of photochemical processing. On the other hand, the increasing trends of mass ratios of C$_2$ to its precursor compounds: ωC$_2$, Pyr, Gly and MeGly as well as C$_3$ (but not C$_4$) diacid (Carlton et al., 2007; Ervens et al., 2004b; Kawamura et al., 1996a; Lim et al., 2005; Warneck, 2003), were found for BA toward to 120 h (Fig. 6a–e and f). It is noteworthy that C$_3$/ωC$_7$ ratios also showed a slight increase, although they are not clear in the later stages of experiment (Fig. 6g), suggesting a potential formation of C$_3$ diacid via ωC$_7$ that is derived from unsaturated fatty acids and/or cyclic olefins. In addition, F/M ratios showed an increase with irradiation up to 48 h in AA and 18 h in BA followed by a gradual decrease until the end of experiment (Fig. 6i), indicating a significant photochemical transformation during an early stage of experiment and decomposition in a later stage.

Photochemical degradation of C$_2$ and C$_3$ diacids should have overwhelmed their photochemical production even in an early stage of experiment, except for few cases (Fig. 3a and b). Based on laboratory studies, C$_2$ and C$_3$ diacids have been reported to decompose in aqueous phase in the presence of Fe$^{3+}$ (and C$_2$ diacid even in the presence of Fe$^{2+}$) under UV irradiation (Pavuluri and Kawamura, 2012; Wang et al., 2010b), but C$_2$ diacid (and maybe C$_3$ diacid) is relatively stable in the absence of Fe species (Pavuluri and Kawamura, 2012). It is well documented that both C$_2$ and C$_3$ diacids tend to form complexes with Fe$^{3+}$ by acting as ligands in aqueous phase, which exhibit a strong light absorbing ability. Although the equilibrium constant of Fe$^{3+}$-malanato complex is slightly lower than that of Fe$^{3+}$-oxalato, both diacids photolyze upon the absorption of UV light to result in Fe$^{2+}$ and CO$_2$ (Wang et al., 2010b; Zuo and Hoigne, 1994).

We found that non-irradiated AA and BA samples contain significant amounts of water-soluble Fe$^{2+}$ and Fe$^{3+}$ species (Table 1). Because high abundance of particulate Fe is present in both AA and BA (Table 1), the concentrations of water-soluble Fe$^{2+}$ and Fe$^{3+}$ species in both AA and BA samples may increase upon UV irradiation; the water-insoluble Fe can be transformed into water-soluble forms by photochemical processing of mineral aerosols (Solmon et al., 2009; Srinivas et al., 2012). In fact, the
mass ratio of C$_2$ diacid to Fe$^{3+}$ is 15:1 in non-irradiated AA and 7:1 in BA, which are close to the ratio (10:1) used in laboratory experiments conducted by Pavuluri and Kawamura (2012) for Fe-catalyzed photolysis of C$_2$ diacid in aqueous phase, in which the photolysis of C$_2$ is very fast ($k = 206 \text{ L mol}^{-1} \text{s}^{-1}$) and 99% of the C$_2$ is degraded in 0.5 h. Therefore, available water-soluble Fe$^{3+}$ (and Fe$^{2+}$) in AA and BA should be enough to promote the catalytic photochemical degradation of C$_2$ (and C$_3$) upon UV irradiation (Fig. 7) and thus the degradation rate of C$_2$ (and C$_3$) should have increased with the prolonged experiment due to enhancement in Fe$^{3+}$ (and Fe$^{2+}$) levels in the given sample.

The concentration of C$_2$ diacid in AA decreased by 30% in 1.5 h and continued to decline by 90% until 12 h (Fig. 3a). On the other hand, the experiment of BA showed that the concentration of C$_2$ decreased by 47 and 51% in 0.5 and 1.5 h, respectively, and then gradually declined. The concentrations of C$_3$ also showed similar trends with C$_2$ (Fig. 3b). Although C$_2$ and C$_3$ diacids decreased sharply during early stages of experiment, they decreased gradually in the later stages, despite possibly enhanced levels of water-soluble Fe$^{2+}$ and Fe$^{3+}$ species. These trends imply that photolysis of C$_2$ and C$_3$ diacids is highly significant in the presence of water-soluble Fe$^{3+}$ (and Fe$^{2+}$) (Fig. 7). On the other hand, the formation of both C$_2$ and C$_3$ diacids is also intensive with the photochemical processing of their precursor compounds in AA and BA. However, the net rate of production or degradation of C$_2$ and C$_3$ diacids in each experiment (Fig. 3a and b) should depend on the abundances of water-soluble Fe$^{2+}$ and Fe$^{3+}$ species and their precursors in AA and BA.

We found an increase in the mass ratios of MeGly to Gly with irradiation toward the end of the experiment, except for an early stage of experiment (up to 6 h) in AA, whereas in BA they remained relatively constant up to 36 h and then increased gradually up to 72 h followed by a rapid decrease (Fig. 6n). As noted earlier, concentrations of Gly and MeGly increased with experiment up to 18 ~ 24 h in both AA and BA. Thereafter, Gly decreased toward the end of experiment in both AA and
BA whereas MeGly remained relatively constant in the AA, but decreased in BA (Fig. 4i and j). Such differences should be caused by the difference in their production rates depending on the concentrations of potential precursors and their oxidation products in AA and BA: benzene and glycolaldehyde for Gly, acetone and higher alkanes (\(>C_3\)) and alkenes (\(>C_2\)) for MeGly (Fu et al., 2008). Because photochemical oxidation of MeGly \((k_{OH} = 1.72 \times 10^{-11} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1})\) is higher than Gly \((k_{OH} = 1.14 \times 10^{-11} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1})\) (Carter and Atkinson, 1996), abundance of MeGly in AA than Gly can be attributed to its enhanced production than the later species during photochemical processing of aqueous aerosols derived from anthropogenic sources.

### 3.5 Possible photochemical pathways of long-chain diacids and oxoacids

Enhanced concentrations of normal and branched \(C_4\)-\(C_7\) diacids during an early stage (18 \(\sim\) 36 h) (Fig. 3c–f) may be caused by photochemical oxidation of the first generation products derived from the oxidation of anthropogenic and/or biogenic VOCs (e.g., cycloalkenes, monoterpenes, and sesquiterpenes) and unsaturated fatty acids (Gao et al., 2004; Kalberer et al., 2000) (Fig. 7). They should be further oxidized to result in lower diacids (Kawamura et al., 1996a; Matsunaga et al., 1999). The relatively constant levels of \(C_5\), \(iC_4\) and \(iC_5\) during 36 and 72 \(\sim\) 96 h (Fig. 3d, l and m) may be due to the balance between photochemical production and degradation. The increases in the concentrations of \(C_4\) with a prolonged irradiation up to 72 h in BA and 96 h in AA further demonstrates its formation from higher diacids and other precursors in aqueous aerosols (Charbouillot et al., 2012; Kawamura and Sakaguchi, 1999) (Fig. 7). In fact, total diacids stayed relatively constant from 24 to 72 \(\sim\) 96 h (Fig. 3x). In addition, mass ratios of \(C_4\) to \(C_5\)-\(C_7\) showed a gradual increase throughout the experiment (until 120 h) in both AA and BA (Fig. 6k–m). These results support a photochemical breakdown of longer-chain (\(\geq C_5\)) diacids resulting in \(C_4\) (Charbouillot et al., 2012; Matsunaga et al., 1999; Yang et al., 2008b).
In addition, $\omega C_8$ acid, which can be produced by the oxidation of cyclic olefins and unsaturated fatty acids (Gao et al., 2004; Kawamura and Sakaguchi, 1999), showed a gradual increase (Fig. 4e) similar to that of $C_4$ diacid (Fig. 3c) in both AA and BA, suggesting a significant photochemical production of $C_4$ via $\omega C_8$ until the consumption of the precursor compounds derived from anthropogenic and biogenic VOCs and biogenic unsaturated fatty acids (Gao et al., 2004; Kalberer et al., 2000). In fact, ratios of $C_4$ to $C_5$-$C_7$ were 10 times higher in BA than in AA whereas those of $C_4/\omega C_8$ were similar in both the BA and AA (Fig. 6j). However, their temporal profiles with irradiation time are similar in both AA and BA. These results suggest that the formation of $C_4$ and $\omega C_8$ is much higher in biogenic aerosols than in anthropogenic aerosols compared to $C_5$-$C_7$ diacids, but their formation/degradation processes may be similar irrespective of the origin of precursors. However, it is not clear from this study if $C_4$ is mainly derived (via $\omega C_8$) from cyclic olefins or unsaturated fatty acids (Fig. 7).

It is well established that long-chain ($C_8$-$C_{12}$) diacids are formed by photochemical oxidation of unsaturated fatty acids (e.g., oleic acid) (Kawamura and Gagosian, 1987; Matsunaga et al., 1999) (Fig. 7). However, unsaturated fatty acids were not abundant (e.g., oleic acid was 0.89 ng m$^{-3}$ in AA and below detection limit in BA) in non-irradiated samples (Fu et al., 2010). Hence, photochemical formation of long-chain diacids from the oxidation of unsaturated fatty acids should be less important during the experiment, although chemical forms of polymerized and/or partially oxidized unsaturated fatty acids may be abundant in the aerosols. On the other hand, photooxidation rate constant of diacids increases with an increase in carbon number of individual diacids ($\geq C_4$) (Yang et al., 2008b). Hence, photochemical breakdown of $C_8$-$C_{12}$ diacids to lower diacids (Matsunaga et al., 1999; Yang et al., 2008b) should be very likely (Fig. 7). The gradual decreases of aliphatic unsaturated diacids, aromatic diacids, and o xoacids, except for $\omega C_8$, with irradiation are likely caused by the photochemical degradation (Fig. 7).
3.6 Atmospheric implications

As discussed above, this study reveals that photochemical degradation of C$_2$ and C$_3$ (due to Fe-catalyzed photolysis) in aqueous aerosols overwhelmed their production whereas C$_4$ diacid showed photochemical formation. These results are consistent with the recent atmospheric observations: a significant reduction in C$_2$ diacid concentration and an inverse relationship between the C$_2$ and Fe in cloud water (Sorooshian et al., 2013), and the replacement of the predominance of C$_2$ by C$_4$ in the Arctic aerosols (Kawamura et al., 2010, 2012). It was also reported that C$_4$ and C$_5$ diacids are most abundant among C$_3$-C$_8$ diacids determined during the photochemical oxidation of C$_6$-C$_9$ diacids in a laboratory experiment (Yang et al., 2008b).

On the contrary, enhanced degradation of C$_2$ and C$_3$ and formation of C$_4$ diacid upon prolonged irradiation, are not consistent with previous laboratory, observation and model studies on photochemical production and degradation of diacids and related compounds in aqueous phase (e.g., cloud processing) (Carlton et al., 2007; Charbouillot et al., 2012; Ervens et al., 2004b; Kawamura et al., 1996a; Kawamura and Sakaguchi, 1999; Lim et al., 2005; Warneck, 2003). In fact, previous studies did not consider Fe-catalyzed photolysis of C$_2$ diacid, which is significant at least in Fe-rich atmospheric waters. On the other hand, the formation processes and potential precursor compounds of C$_4$ diacid have not been fully explored yet. Moreover, previous laboratory experiments on aqueous solutions of specific species did not consider the mixing state of organic and inorganic constituents in atmospheric aerosols (Ervens et al., 2011), although simplified experiments sometimes provide useful information on mechanisms.

Generally, it has been considered that the anthropogenic contributions of α-dicarbonyls to organic aerosols are minor: 8 % for Gly and 5 % for MeGly (Fu et al., 2008). To the best of our knowledge, their production in atmospheric waters has not well been recognized yet. Our laboratory experiments indicate that the photochemical production of Gly and MeGly is significant in aqueous aerosols. The production of
MeGly is more pronounced compared to Gly with prolonged photochemical processing of aqueous anthropogenic aerosols. Finally, our findings based on the batch laboratory experiment emphasize the importance of the photolysis of C₂ and C₃ diacids and photochemical production of C₄ diacid and α-dicarbonyls in aqueous aerosols to reconcile the current atmospheric model(s) such as cloud parcel model (Ervens et al., 2004a), and to better understand the secondary organic aerosol budget and its climatic impacts.

4 Summary and conclusions

In this study, we conducted batch UV irradiation experiments on anthropogenic (AA) and biogenic (BA) aerosol samples collected from Chennai, India in the presence of moisture for the reaction time of 0.5 to 120 h. The irradiated samples were analyzed for molecular compositions of diacids, oxoacids and α-dicarbonyls. Concentrations of C₂ and C₃ and C₈-C₁₂ diacids decreased with an increase in 12–24 h. In contrast, C₄ diacid (and C₅-C₇) showed a significant increase with reaction time up to 72 h in BA and 96 h in AA. Oxoacids and α-dicarbonyls showed a significant increase during an early stage of irradiation followed by a gradual decrease in the prolonged experiment, except for ωC₈ acid that showed a pattern similar to C₄ diacid and for methylglyoxal that remained relatively abundant from 24 h to the end of the experiment in AA. The mass ratios of C₂ diacid to its precursors: glyoxylic acid, pyruvic acid, α-dicarbonyls (glyoxyal and methylglyoxal) and C₃, showed a considerable increase with irradiation, while those of C₄ to C₅-C₇ diacids and ωC₈ acid and methylglyoxal to glyoxal in AA showed a significant increase with irradiation. These results demonstrate that degradation of C₂ and C₃ (and C₈-C₁₂) and formation of C₄ (and C₅-C₇) is enhanced with photochemical processing of aqueous aerosols. This study further infers that iron-catalyzed photolysis of C₂ and C₃ diacids and photochemical formation of C₄ diacid via ωC₈ acid derived from cyclic olefins and/or unsaturated fatty acids play an important role in controlling their abundances in the atmosphere with photochemical processing of aqueous...
Formation and degradation of diacids and related polar compounds

aerosols. This study also suggests that photochemical production of α-dicarbonyls, in particular methylglyoxal, in anthropogenic aerosols is significant.
