SUPPLEMENTARY MATERIAL

FIGURES

Figure S1. Selected regions for retrieval of OMI Tropospheric Column NO₂ in yellow: (a) area along the S–N axis (~3,040 km²) which includes northern Barcelona Metropolitan Area (BMA), the Vic Plain and an area of the Pre-Pyrenean range to analyze quantitatively the time trends and patterns and (b) across Western Europe (~6,514 × 10⁶ km²) to analyze qualitatively the NO₂ spatial patterns in the two scenarios considered (when the amount of O₃ in the Vic Plain is high and when it is low).
Figure S2. (a) Spatial variability of mean June–August NO (a) and NO₂ (b) concentrations observed in selected AQ sites. Data from Ciutadella (CTL), Palau Reial (PLR), Montcada (MON), Granollers (GRA), Montseny (MSY), Manlleu (MAN), Tona (TON), Montsec (MSC), Bellver de Cerdanya (BdC), Berga (BER), Mataró (MAT), Manresa (MNR), Vilanova i la Geltrú (VGe), Constantí (CON) and Alcover (ALC) air quality monitoring stations.
Figure S3. Normalized $O_3$, NO and NO$_2$ cycles and wind patterns for July (wind coming direction in the left vertical axis and wind speed in the right vertical axis). Pollutants’ concentrations ($O_3$, NO and NO$_2$) are normalized to the highest average value to emphasize the shape of the cycles, in the case of more than one $O_3$ cycle in a graph (b and d plots), the $O_3$ concentrations are normalized to the highest $O_3$ values of the site that measured them. July average wind speeds and directions data come from meteorological stations located near the corresponding AQ sites (air quality CTL monitoring site with meteorological BCN; air quality MON and GRA monitoring sites with meteorological PTS; air quality MSY monitoring site with meteorological TAG; air quality TON, VIC and MAN monitoring sites with meteorological GUR; air quality PAR monitoring site with meteorological NUR). The map shows the location of air quality monitoring sites (white codes; squares) and close meteorological sites (red codes; circles) grouped by pointed circles. Air quality data are from monitoring sites along the S–N axis. In general, the highest $O_3$ levels occur when the wind blows from the south (location of the Barcelona Metropolitan Area, BMA) at its maximum velocity, confirming the clear influence of the BMA plume transport.
